Hypoprothrombinemia Following Propylthiouracil Treatment.—Severe hemorrhagic diathesis appeared during the course of propylthiouracil treatment for thyrotoxicosis in a girl 16. The fundamental defect was transient, pronounced prolongation of the prothrombin time. The prothrombin deficiency occurred as an isolated phenomenon without evidence of liver damage or depression of white blood cells. The actual deficiency proved to be mainly one of accelerator globulin. Treatment with fresh human serum caused a fall in prothrombin time and cessation of hemorrhage. The hemorrhagic tendency was controlled with fresh serum and blood, and a subtotal thyroidectomy was successfully carried out. The temporary nature of the hypoprothrombinemia in the absence of a disturbance of hepatic function strongly suggests the type of reaction due to drug intoxication. No previous incident of isolated prothrombin deficiency without other signs of hepatic damage has been noted after the use of thiourea derivatives.

Corticotrophin in Nephrotic Syndrome.—Fourteen patients aged less than 16 with the nephrotic syndrome were treated with corticotrophin (ACTH). All showed the classic features of anasarca, hypoproteinemia, massive proteinuria, and hypercholesterinemia. The drug was administered intramuscularly in doses of 60 mg. daily in four divided doses of 15 mg. every six hours, for four to six days. Five patients given eight courses showed complete clearing of edema in seven instances, one patient showing no response to a second course. Four patients given six courses showed significant but incomplete clearing of edema each time. Five patients showed no clinically significant response to seven courses. The type of diuresis with regard to salt and water excretion was similar to that seen in spontaneous diuresis. All but one of the patients who failed to have a clinically significant response did, nevertheless, show a slight sodium diuresis after withdrawal of the drug. There were no consistent changes in the significant chemical findings in the blood, except that in most cases, regardless of clinical results, a drop in the total cholesterol level was observed after treatment. In several patients who received sodium lactate by mouth following diuresis edema did not develop and there was a pronounced increase in the urinary sodium. This suggests that at least temporarily their kidneys were capable of dealing with sodium in normal fashion. The patients were followed up for seven to 15 mo. after treatment. Some remained symptom-free, others relapsed several times but responded to subsequent periods of treatment, and still others after early successes failed to respond to later administration of corticotrophin. Only one of the group showed clearing of the urine suggesting a permanent remission. Thus the hormone at best offers only a means of controlling edema of the nephrotic syndrome. Whether its repeated use may alter the over-all prognosis can only be determined after a much longer period of observation. But even if not curative, corticotrophin permits the induction of diuresis with fair regularity under controlled conditions and thus should prove a useful tool in the study of the mechanism of diuresis.

Aerobacter Infections on Infants' Wards.—A self-limited outbreak of infection due to a previously undescribed encapsulated gram-negative rod is reported on. It occurred in the course of a study on the control of airborne infection carried out on two infants' wards, one being kept as a control ward, while triethylene glycol was vaporized in the test ward. The morphological and cultural characteristics of the pathogen place it in the Aerobacter-Klebsiella group. It was readily identified by its capsular swelling in the presence of serums against types 23 and 32 pneumococcus. Serologic studies showed it to be antigenically related to certain other strains of encapsulated, gram-negative rods, but not to Friedländer's bacillus, Hemophilus influenzae, meningococcus, or pneumococcus other than the types mentioned above. In some of the patients who acquired the organism mild respiratory infections or diarrhea developed, accompanied by fever, but most patients remained asymptomatic. The organism spread in epidemic fashion on both glycolized and control wards and was recovered from the nasopharynx of 50 of a total of 361 patients included in the study, also from many nurses, attendants, and visitors. In the course of the epidemic the ward environment (air, dust, furniture, and bedclothes) became heavily contaminated. It is postulated that patients with profuse nasal discharge and diarrhea may have served to infect the ward environment, which in turn served as the source of infection to other patients.

Radioactive Iodine in Treatment of Angina Pectoris.—The effect of radioactive iodine (I^{131}) on severe angina pectoris was studied in 28 presumably euthyroid patients who had received 15 to 20 mc. of the drug. All patients were followed for six months to two years. All had been previously treated for long periods by conventional methods, either without satisfactory improvement or with actual increase in symptoms. Many had had one or more recognized attacks of myocardial infarction. Six others had aortic valvular disease with great enlargement of the left ventricle. Nine had had congestive heart failure, and nine had fairly severe hypertension. Of the 28 patients, 10 died, but there was no evidence that radioactive iodine had anything to do with the deaths. The possibility that deposition of cholesterol in coronary arteries may be accelerated after thyroid function is depressed cannot be excluded. Of the remaining 18 patients, results were arbitrarily designated as good in 12, fair in four and unsatisfactory in two. Until more time has elapsed, the duration of beneficial effects cannot be determined. In many of the authors' cases improvement was maintained for over a year. The authors are convinced that radioactive iodine has a place in the treatment of severe, otherwise intractable angina pectoris, as well as in certain cases of severe congestive heart failure or abnormal cardiac mechanisms with poorly controlled tachycardia. A tracer dose should always precede treatment, affording a rough estimate of what the treatment dose will accomplish. The criteria for the selection of patients with angina pectoris for treatment with radioactive iodine cannot be established until much more experience with this method of treatment has accumulated and, if possible, procedures developed by which the effect on the thyroid gland can be predicted more accurately.

Dramamine in Radiation Sickness.—Because dimenhydrinate (dramamine) had proved effective in the nausea and vomiting of motion sickness, it was administered to 100 patients with radiation sickness following deep roentgen therapy. It was given half an hour before each meal and at bedtime, as soon as symptoms appeared. Since all radiation treatments were given between 8:30 a. m. and 12:30 a. m., the maximum time elapsing between a treatment and any one dose of dimenhydrinate was two hours, and in the majority of instances the interval was much shorter. Symptoms of radiation sickness appeared on an average of 5.3 days after treatment had been instituted. In only 46 of these 100 patients was improvement noted. One-half of this number had no recurrence of symptoms after administration of the drug for one day (400 mg.). In the rest, it had to be given daily throughout the period of irradiation. In the latter group symptoms recurred on an average of 2.1 days after the drug was discontinued. Placebos could be given at intervals during irradiation in 24 of the 46 patients claiming improvement with dimenhydrinate. Seventeen of the 24 patients did as well with the placebo as with the drug itself, reducing the number of patients whose improvement could be credited to dimenhydrinate to 29.

Hormones and Castration in Breast Cancer.—According to Nathanson, surgery and irradiation remain the preferred methods for permanent or palliative control of localized and accessible manifestations of breast cancer. There is now indisputable evidence that the course and character of some breast cancers may be retarded or accelerated by administration or deprivation of sex hormones. There is no evidence that sex hormones or castration result in permanent control of even the most susceptible cancers of the breast, for the effects are temporary and usually of short duration. Consequently, the administration of androgens and estrogens as well as castration can be considered as a third method of attack, but only from the standpoint of palliation. It is of greatest value when the disease is beyond the realm of possible benefit from established procedures. Some advanced primary breast cancers may be rendered susceptible to palliative surgical attack when significant regressions occur after castration or hormonal therapy. Estrogens given in conjunction with irradiation may enhance the effect of irradiation. In addition, partial regression of lesions after initial treatment with estrogens may permit even more effective radiation therapy, made possible through the use of smaller portals. Estrogen therapy of recurrences within an area of previous and initially effective irradiation is ordinarily not as efficacious as it is for similar untreated lesions. Irradiation therapy of localized osseous metastases from breast cancer may alleviate pain and promote calcification of osteolytic lesions that initially respond to hormonal therapy and undergo reactivation or are primarily hormone-resistant. Contrariwise, hormones or castration may favorably influence osseous metastases that are resistant or recrudescent after preliminary irradiation. The possibility of serious complications with intensive hormone therapy emphasizes the extreme caution that must be exercised during the entire treatment period. The effects of hormones on breast cancer seriously challenge the long-held concept of autonomy of the cancer cell. The observations indicate that some cells judged neoplastic by classic definitions are apparently susceptible to direct attack or through changes in their environment by agents that are essentially physiological in action.

*Histoplasmin and Coccidioidin Sensitivity in Norway. J. Böe, V. Lindén and J. Tveit.—p. 196.

Histoplasmin and Coccidioidin Sensitivity.—Histoplasmin, coccidioidin, and tuberculin sensitivity tests were done in 1,074 persons, of whom 935 were patients in medical and surgical wards and 139 physicians, nurses, and medical students. Nearly all the patients were afebrile when the tests were performed, and most of the persons examined were adults. Twenty-seven persons had positive results from histoplasmin alone and three from coccidioidin alone. There were 23 persons with positive results from both histoplasmin and coccidioidin. None of the 53 positive reactors showed any signs of disease of the lungs or other disease that could be associated with a mycotic infection. Fifty of these 53 persons also had positive results from tuberculin. Consequently, systematic examinations for pulmonary calcifications were omitted as not likely to be instructive. The three persons who were observed to be tuberculin-negative and mycotic antigen-positive showed no pulmonary calcifications. There are reasons for believing that some of the positive reactions to histoplasmin were caused by past or present infections with Histoplasma capsulatum. One of the three persons with a positive reaction to coccidioidin alone had spent some time in Southern California and thus could have been infected with coccidioidomycosis. The relatively large number of persons with positive reaction to both histoplasmin and coccidioidin indicates that in these cases the positive reactions must be regarded as cross reactions due to systemic infections with one or more unknown fungi immunologically closely related, possibly Geotrichum. It seems probable that one or several systemic fungous infections occur in Norway and that they give positive reactions to both histoplasmin and coccidioidin.

*Report on Immediate Results of Experiment on BCG Vaccination Against Tuberculosis. P. Cattaneo and R. Scotti Douglas.—p. 3.
*Clinical Considerations in a Case of Tuberculosis of Pubis. A. Amadei.—p. 52.

BCG Vaccination in Children.—Cattaneo and Scotti Douglas observed 633 children of both sexes between the ages of 4 and 14 yr. with a negative Wollmer test. The children were observed for three months in a municipal sanatorium located at high altitude in Italy in three approximately equal groups. Twenty-seven children of the first group, 40 of the second, and 39 of the third had had contact with tuberculosis in their homes. Roentgenographic examination of the thorax showed early tuberculous lesions in 72 children (11%). The tuberculin tests were repeated at monthly intervals before and after vaccination. The Wollmer test was used exclusively with the children of the first group, and the Mantoux test was used with those of the second and third groups. BCG vaccination was performed only in 556 children, 77 children being excluded because they had febrile intercurrent diseases before vaccination or because they had a 3+ reaction to the Mantoux test. The focus of reaction to vaccination was acute in 250 children (45%), mild in 15 (2.7%), and moderate in the rest. The tuberculin tests performed one month after vaccination gave positive results in 11.82% of the children in the first group (Wollmer) and 94.9% in the children of the second and third groups (Mantoux). It was observed that the positivity of the postvaccinal tuberculin tests and the improvement of health of the children after vaccination were directly related to the extent of the reaction of the focus of BCG vaccination.

Tuberculosis of Pubic Bone.—Tuberculosis of the pubic bone is rare. Clinical diagnosis is difficult; however, in most cases the roentgen picture of the pubic bone is clear and characteristic of the disease, showing a pubic symphysis with irregular borders and decalcification of the pubic bone. The author discusses the clinical course and treatment of the various forms of tuberculosis of the pubic bones, namely, (1) early closed forms, (2) tuberculous abscess without fistula, (3) tuberculous fistula, either with or without sequestrums, and (4) great destruction of the pubic bone in cases of long duration. The surgical treatment in cases of tuberculosis with caries of the pubic bones with fistulas and multiple tuberculous abscesses consists of removal of the segments of the carious bone and scraping of the carious foci. The abscesses permanently regress, and the fistulas heal after operation. Orthopedic-surgical treatment with use of Blair's or other types of arthrodesis is indicated in cases with severe static and dynamic disorders from severe loss of bone due to tuberculosis. The author reports a case in a woman of 23 in whom the presence of a hard and elastic swelling in the suprapubic region led to an erroneous diagnosis of either encapsulated hematoma or desmoid tumor. A roentgenogram showed tuberculosis of the pubic bones. Multiple tuberculous abscesses and a tuberculous fistula were present. Cure was effected by surgical treatment consisting of removal of sequestrums and scraping of carious bones.

Methonium Compounds in Hypertension.—Thirty-four patients with essential hypertension were given a therapeutic trial with pentamethonium bromide or hexamethonium bromide. Women predominated in a ratio of 2 to 1. Before treatment each patient was given two weeks' control period of observation, routine treatment, and bed rest. Initially the methonium compounds were given intramuscularly in doses of 25 mg. to 150 mg. at intervals of two to six hours, depending on the response of the patient. After two weeks the drugs were given by mouth in doses of 500 to 1,000 mg. of pentamethonium bromide every four or six hours, or 250 to 500 mg. of hexamethonium bromide given eventually as frequently as every two hours. After 24 to 72 hr. of oral treatment the patient was allowed to get out of bed. After they were discharged from the hospital the patients continued to take more than 3 gm. of hexamethonium or pentamethonium bromide daily in divided doses at two or three hour intervals. In every case the methonium compounds were hardly more effective in lowering the blood pressure than the initial period of bed rest. Follow-up of these patients showed a complete failure of the drugs to lower or maintain a low blood pressure when orally administered. One patient with malignant hypertension became unconscious within 15 min. after intramuscular injection of 25 mg. of pentamethonium bromide and died two hours later. There were three probable cases of bromide intoxication. Although methonium compounds given intramuscularly produced an acute drop in blood pressure when the systolic pressure exceeded 200 mm. of mercury, the effect did not last. Almost all patients who continued taking the drug claimed partial or complete relief of many of their symptoms, such as headache, dyspnea, or vertigo, even in the absence of any appreciable fall in their blood pressure or objective improvement. It is believed that the sedative effect of the bromide ion, aided by ancillary factors, was one of the main agents in the subjective improvement of these patients. Since the methonium compounds are not harmless and produce results no better than bed rest, there is no indication that they should be used at all outside of the hospital. The therapeutic value of these drugs in the long-term treatment of hypertension should not be assessed by their known ability to produce an acute fall in blood pressure.

Streptomycin in Tuberculous Meningitis.—Of 54 patients with tuberculous meningitis treated with streptomycin during the period of July 1947 to May 1948, 18 survived and were followed up for two and a half to three and a half years. Two of the 18 original survivors died, reducing the survival rate to 30%. Three patients relapsed but recovered after further treatment with streptomycin. Sequelae shown by the survivors were deafness in two children, minimal hemiplegia in one child, retarded development in one, and an intellectual defect in one. Audiometric and vestibular tests were carried out on 14 of the 16 survivors. All showed complete loss of vestibular response during caloric tests, yet none showed clinical ataxia in a good light. Some patients were slightly ataxic with the eyes closed or in the dark. Audiometric tests revealed a pronounced hearing loss in one patient and a loss up to 50 db. in another. In the remainder the audiograms were normal. Later manifestations of nonmeningeal tuberculosis, presumably due to sporadic hematogenous dissemination of tubercle bacilli, occurred in two recovered patients. The nonmeningeal lesions of these patients responded to treatment and were not accompanied by any evidence of recrudescence of meningitis. Slight variations in the cerebrospinal fluid of the survivors were observed, but their significance could not be determined. The authors do not regard a patient as finally cured even two and a half years after streptomycin treatment. A further, undetermined period of observation is necessary.

Thiosemicarbazones in Tuberculosis.—Sixteen male and nine female patients, 14 with moderately advanced and 11 with far advanced pulmonary tuberculosis, were treated with amithiozone ("contibiol"). Treatment was planned to continue for three months. Each patient received a daily dose of 50 mg. for the first week, 100 mg. for the second week, and 200 mg. for the remainder of the course. Of the 25 patients, only 17 were able to complete the course, because of subjective toxic symptoms in four patients, of roentgenologic evidence of extension in two, and severe neutropenia in two. In three of the patients with subjective toxic symptoms an attempt was made to continue treatment by a reduction in the daily dose to 100 mg., but even this reduced dose was not tolerated. Only three of the 25 patients gained weight during treatment, the rest lost weight in amounts varying from five to 17 lb. (2.3 to 7.7 kg.). Ten patients showed roentgenologic improvement at the end of the study. The changes consisted of some measure of resolution of the exudative component, similar to those noted with paraaminosalicylic acid. In four of 20 patients with sputum positive for tubercle bacilli at the beginning of the treatment, the sputum became negative, but in 16 tubercle bacilli were still demonstrated at the end of the course. All patients felt some degree of malaise during treatment, and all felt better when the drug was discontinued. Twenty-two patients complained of nausea, 15 of vomiting, two of diarrhea, and two of headache. Twelve patients had drug fever, that is, a persistent elevation of temperature to 99.5 F. Sixteen patients had less striking manifestations, including chills, watering of the eyes, periorbital edema, pruritus, and enlargement of cervical lymph nodes. Six patients had significant proteinuria, presumably indicating some degree of renal irritation. Anemia occurred in five patients, all of whom had a normal blood picture at the start of the treatment. In two patients almost complete neutropenia developed. Because of the equivocal therapeutic results and the toxic effects, the authors believe that the drug has no advantage over other therapeutic agents, such as streptomycin and paraaminosalicylic acid, and that it is too toxic for general use. If used at all, it requires more stringent laboratory supervision than is usually available.

Pathogenesis of Multiple Glomus Tumors.—A girl 13 is reported on who since her early childhood had had a developmental defect of the right arm resulting in extensive functional disturbance of the right hand. Peculiar features of the disease process were the occurrence of multiple painful glomus tumors on the right forearm and hand, varying in size from that of a bean to that of a dove's egg; pronounced weakness and atrophy of the muscles of the right upper arm and forearm; isolated hyperhidrosis in the involved forearm and fingers; hypoplasia and chronic osteoporosis of the bones of the forearm and of the hand, with precocious bony closure of the epiphyseal lines; pronounced brachymetacarpia of the fourth and fifth finger. The predominant multiple glomus tumors were histologically of the angiomatous type. An intrinsic relationship is suggested between the glomus tumors and the local disturbance of bone growth, for which the term "glomangiomatous-osseous malformation" has been coined. The mesenchymal tissue, especially the glomus and bone tissues, may be considered as primarily affected by the local degeneration. This new congenital developmental disturbance is similar to other congenital systemic diseases, such as systemic hemangioma and neurofibromatosis (von Recklinghausen's disease). Consequently, the isolated occurrence of multiple glomus tumors in the absence of any other malformation may be a congenital disturbance of development of the glomi of blastomatous type rather than genuine blastoma. "Glomoblastosis," therefore, seems to be a more exact term for multiple glomus tumors.

*Effect of Transplantation of Hypophysis on Regulation of Carbohydrate Metabolism. H. zur Horst-Meyer.—p. 401.

Hypophysis and Regulation of Carbohydrate Metabolism.—The relation of the hypophysis to the hypothalamic center that regulates carbohydrate metabolism was investigated in 36 patients (nine men and 27 women) with definite symptoms of diencephalohypophysial disturbance. Approximately half of these patients had a disturbance of the carbohydrate metabolism. It was characterized in two patients by the failure of the blood sugar level to rise normally after a single oral dose of dextrose. In all patients there was a greater elevation of the blood sugar level after the second than after the first dose of dextrose. The terminal blood sugar values two hours after the second dose of dextrose were higher than the initial values. This absence of immediate hyperglycemia after the administration of dextrose, as well as the suppression of the compensatory hypoglycemic mechanism, occurred in the same percentage of men as of women. These patients were given intramuscular injections with pulverized anterior pituitary lobes from calves, suspended in isotonic sodium chloride solution. The first changes in the blood sugar curve were observed within one to three weeks after these injections. In the two patients whose blood sugar level was not previously elevated after the first dose of dextrose a normal elevation now occurred. An increased counterreaction was observed in all patients: the increase in the elevation of the blood sugar level after the second dose of dextrose did not exceed that after the first dose, and the terminal values were the same as the initial values. A definite explanation for this activation of the counter regulation cannot yet be given. It is suggested that the agent responsible may be liberated with the absorption of the injected hypophysial tissue. An inflammatory infiltration around the area of injection may prevent its effect. The natural agent was absent in the author's patients but could be replaced by the injection of the animal hypophysial tissue. Thus there appears to be a fundamental difference between the therapeutic effect of hypophysial tissue and extracts of anterior pituitary lobe. The latter is known to have an anti-insulin effect.

Pentolysis in Diagnosis of Cancer.—Preliminary experiments showed that the serums of patients with various acute or chronic noncancerous diseases, such as tuberculosis, fibromas, and benign tumors, cirrhosis of the liver, and diabetes mellitus had little or no effect on pentoses that had been added to these serums. On the contrary, dry pentoses added to the serums of patients with cancer were disintegrated by these serums, and lactic acid and glycolic aldehyde were produced. Graphs of the effect of cancerous serums on the pentoses were studied and proved to be typical of an enzymatic action. Additional experiments demonstrated that the addition of serum of normal persons to that of the cancerous patients inhibits the pentolysis. The serums of persons with infectious diseases occasionally exerted a pentolytic effect that could not be inhibited by the addition of serums of normal persons. This effect may be ascribed to the action of bacteria or of their dissolution products. When cancerogenic injections were given to rats, blood withdrawn from these animals by intracardiac puncture definitely showed pentolysis 30 days after the injection, while necropsy of the animals killed revealed no tumor. It is suggested that pentolysis is a precocious reaction that occurs before any tumor has had time to develop. Four hundred and sixty-two blood tests were performed on 399 patients with cancer or other diseases, including those patients on whom the preliminary tests were performed. A positive pentolytic reaction to these tests confirming the diagnosis was observed in 414 instances. The enzymatic nature of the phenomenon is stressed.

Chloramphenicol in Pertussis.—Ninety-seven infants and children and three adults with whooping cough were treated with chloramphenicol (chloromycetin®). All these patients showed the characteristic clinical picture of the disease, and in 80 of them the diagnosis was confirmed by the cultivation of Hemophilus pertussis. In 93 patients the chloramphenicol was administered rectally in suppositories, whereas the seven older children and the adults were given the drug orally in capsules. Treatment was continued for three to five days. Most of the patients were in the first two or three weeks of the disease. Repeated nasopharyngeal cultures were examined in every case. Of the 80 patients with positive cultures before treatment, 73 had negative cultures within nine days of the institution of the treatment with chloramphenicol. The frequency of the paroxysms fell sharply, and the patients' general condition improved rapidly. The results obtained with the conventional cough-plate method were compared with those of swab cultures from the nasopharynx on the same mediums. The swab cultures gave a much higher percentage of positive results than the cough plates; swab culture was therefore adopted as the routine method of diagnosis. Of 45 strains of H. pertussis in which the in vitro resistance to chloramphenicol was estimated, all were observed to have a low resistance. Chloramphenicol seems to be the most effective drug so far tried in whooping cough. It should be used in every case of pertussis in infants.

Suppressive Treatment of Whooping Cough With Chloramphenicol in Contacts.—Thirteen children who were susceptible contacts of known cases of whooping cough and were in the preparoxysmal stage were treated with chloramphenicol (chloromycetin®). The daily dose was 22 mg. per kilogram of body weight, except for one patient who was given 33 mg. per kilogram of body weight. The drug was given mixed with jam or milk by mouth in five divided doses daily for five days. In 10 of the 13 contacts the disease was arrested in the preparoxysmal stage. In three of the four patients reported on in detail infectivity appeared to be pronouncedly curtailed. The protection given is immediate in contrast with that provided by vaccines, which takes some weeks to develop. A recurrence was observed two weeks later in one patient, and reinfection occurred in another patient after two months, suggesting that when the disease is arrested by chloramphenicol in the preparoxysmal stage it may not be followed by immunity. During the same period 63 children with whooping cough not treated in the preparoxysmal stage served as controls. A severe paroxysmal cough was reported in 14, and 45 were whooping. In only four patients did the cough not cause severe distress. The use of chloramphenicol in the preparoxysmal stage might be valuable in reducing the mortality and morbidity of whooping cough and in controlling the infection.

Pink Disease in Older Children.—Cheek believes that pink disease (acrodynia) may be a manifestation of adrenal dysfunction either primary or secondary to renal disturbances. He found low levels of plasma sodium and urinary chlorides in his acute cases and observed that these abnormalities persisted in some children who were under stress after the typical symptoms of photophobia, hyperhidrosis, irritability, swelling and redness of the hands and feet, and skin rashes had disappeared. Eleven such children between the ages of 2 and 7 years showed the syndrome of the nervous child and exhibited allergic manifestations with eosinophilia. Recovery followed the administration of sodium chloride alone in the mild cases (plasma sodium level 300 mg. per 100 cc.) and followed the administration of 5 mg. of desoxycorticosterone daily in the severe cases. Salt alone did not restore normal osmotic relationships in most cases. There was no abnormality of the blood epinephrine content in 18 children with pink disease. The author speculates that some toxic or photodynamic agent may injure the renal tubules in this disease, altering electrolyte excretion and placing a strain on the adrenal because of its role in maintaining homeostasis.

Role of Adrenal in Pink Disease.—Williams and co-workers found no constant or significant disturbance of the serum sodium content of 22 patients with pink disease (acrodynia) as compared with 22 normal children of the same age, although two patients had a low serum sodium level. The hematocrit, hemoglobin, and protein values were raised, and the serum chloride level was lowered in pink disease, but the mechanism of these changes was not clear. There was no evidence of hypofunction of the adrenal gland as determined by studies of blood sodium and potassium levels and 11-oxysteroid excretion in the urine. A controlled clinical experiment on 10 selected patients failed to show any really significant difference in the recovery rate of the five treated with salt and desoxycorticosterone as compared with those who did not receive this treatment.

Twelve Cases of Nonspecific Inflammatory Articular Lesions Treated According to Lewin and Wassen Technique. L. Benacchio.—p. 192.

Resuscitation by Intracarotid Blood Transfusion.—The authors discuss the method of intracarotid blood transfusion directed toward the brain for resuscitation of human beings. The transfusion is made through the common carotid artery. This method is based on results of a large number of experiments in animals; its purpose is to supply the brain with blood more rapidly than is possible with intraarterial blood transfusion directed toward the heart. An exceptional case of resuscitation effected by this new method is reported. A woman, 53, with neoplasm of the pancreas showed signs of grave intolerance followed by collapse during the preoperatory segmental peridural anesthesia. Administration of the common analeptics, of oxygen through the trachea, and of an intracardial injection of 1 cc. of a 1% epinephrine solution failed. There was no sign of life, and the patient was pronounced dead. Thirty minutes later intracarotid blood transfusion toward the brain was effected. The common carotid artery was empty and pulseless before transfusion, which was given in doses of 50 cc. of citrated blood of group O every 10 min., up to a total quantity of 400 cc. of blood. Resuscitation was effected by this means for the first time in man. Cardiac pulsations and respirations were resumed, and blood pressure returned to normal. However, the patient was comatose and paralyzed, and after 25 hours she died. The authors believe that intracarotid blood transfusion is the therapy of choice in such cases and should be preferred even to massage of the heart.

Sensitization to Etolein. T. Hendelberg.—p. 394.
Surgical Treatment of Mastitis During Lactation. A. Sjövall.—p. 397.

Adrenocortical Activity and Immunity.—Bjørneboe reviews experiments concerning the effect of cortisone and corticotrophin (ACTH) on the concentration of circulating antibodies. To explain the beneficial effect of adrenocortical hormones in human diseases the following hypothesis is proposed: In diseases where antibody formation is injurious, substances that inhibit antibody formation, i. e., adrenocortical hormones, will be effective. In infectious diseases in which the course clearly shows the prognosis to depend on the ability of the organism to form antibodies, adrenocortical hormones will not be effective.

Hypopotassemia.—Osnes discusses three cases of certain hypopotassemia, one case of probable intracellular potassium deficiency, and a fifth case of probable hypopotassemia, in which the pathological-anatomic changes in the heart resemble those described in the literature. In the first two cases, with diarrhea, the hypopotassemia is attributed to dehydration and increased potassium loss in the feces; in the third, with chronic nephritis, the increased loss of potassium via the kidneys is ascribed to the nephritis. The fourth case, with alkalosis, illustrates the significance of potassium in the acid-base equilibrium. In all cases there was disturbance in the intracellular metabolism. Electrocardiographic changes led to the examination of the potassium values in the serum. These changes—prolonged Q-T interval, flattened to negative T waves, prominent U waves and falling S-T segments—all testify to hypopotassemia. The ventricular extrasystoles that were demonstrated in the third case and disappeared after potassium therapy may have been due to the hypopotassemia. Possible shock should first be counteracted.

Primary Pulmonary Sarcoma. H. Nilsson.—p. 440.

Obstetrical Considerations in Essential Hypertension.—Nordenstrahl says that in essential hypertension it is sometimes difficult during pregnancy to differentiate between hypertension, hypertension with superimposed toxicosis, and early simple toxicosis. The effect of hypertension in pregnancy is mainly threefold: intrauterine death is frequent, the infant's weight is less than the weight corresponding to the duration of the pregnancy, and there is definite danger of toxicosis. With blood pressure of 160/100 or more during the first half of pregnancy, renal function tests should be made; if filtration is reduced the pregnancy can be allowed to continue only under the strictest control. Blood pressure increase to 150 or 160 during pregnancy requires only weekly observation from the sixth month on. When the blood pressure is over 170/95 during the later part of pregnancy the critical period for fetal death is between the fifth and fourth week before parturition. For delivery of a living child birth should be induced by rupture of the membrane in multiparas and cesarian section should be done in older primiparas. If bed rest and other treatment can bring the blood pressure down to 170/100, natural delivery may be awaited, but hospital care during the last six weeks is necessary. Prophylactic vitamin C and vitamin D medication in all cases of essential hypertension is believed to be important if given in sufficiently large doses to reduce the fragility of the blood vessels and the tendency to premature separation of the placenta.

*Unusual Form of Surgical Splenomegaly: Anatomicoclinical Definition and Interpretation of Giant Follicular Splenomegaly. L. Tonelli.—p. 1.

Giant Follicular Splenomegaly.—According to Tonelli this disease is an unusual form of splenomegaly in which splenectomy is indicated. The symptoms are similar to those of Banti's syndrome. The spleen is greatly enlarged. The author performed splenectomy on two patients in whom the clinical course and the type of follicular hyperplasia were typical of giant follicular splenomegaly (Ferrata-Introzzi). Both patients had moderate hypochromic anemia. One had leukopenia with lymphocytosis. Giant follicular hyperplasia was restricted to the spleen and a supernumerary spleen in one case and to the spleen and the splenic and pancreatic lymph nodes in the other case. One of the patients died from bronchopneumonia 22 days after the operation. All the lymph nodes were found to be normal at necropsy. The patient with the splenolymphonodular form of the disease is in good health up to now, more than two years after splenectomy. The author believes that giant follicular splenomegaly is the pure splenic form of follicular lymphoblastoma (Brill-Symmer's disease). It is rare and malignant. The mixed splenic and lymphonodular form and the pure lymphonodular form of the disease are frequent, and their malignancy is similar to that of the pure splenic form. Survival for more than eight years after splenectomy has been reported in rare instances. Sooner or later the disease progresses into a malignant form, the early characteristics of the disease remaining or changing into lymphosarcoma, lymphadenosis or lymphogranulomatosis (Sternberg's lymphogranuloma). Therefore, roentgen treatment should follow splenectomy in all cases.

*The Management of Patients with Multiple Sclerosis. B. B. Spota and D. Brage.—p. 815.

Treatment of Multiple Sclerosis.—Spota and Brage review the various theories on etiology of multiple sclerosis and the unsuccessful therapeutic methods used up to now. They suggest that multiple sclerosis is a syndrome of lack of adaptation of the nervous system in persons with reticuloendothelial mesenchymal disease. The authors treated multiple sclerosis with small doses of desoxycorticosterone acetate combined with large doses of ascorbic acid, and they obtained gratifying results from early therapy. They stress the importance of protecting the mesenchyme and avoiding the use of drugs that may injure or destroy it, since multiple sclerosis itself produces demyelinization and microglial reaction. Cortisone therapy for the treatment of multiple sclerosis is suggested by the authors, who have some experiments in process, although they make no definite conclusions. Exact doses used by the authors are not specified.

*Study of Thermal Coagulation Test of Serum Proteins in 398 Cases: Its Diagnostic Value in Cancer, Malignant Hemopathies and Tuberculosis. A. Tzanck and J. P. Soulier.—p. 517.
Risk Associated with Deep Needle Puncture Procedures in Course of Anticoagulant Therapy: Massive Retroperitoneal Hemorrhage from Lumbar Sympathetic Block. J. J. Welti and R. Breynaert.—p. 518.

Diagnostic Value of Thermal Coagulation Tests of Serum Proteins.—Thermal coagulation tests of serum proteins were performed on 164 normal persons, on 89 patients with cancer, on 92 with hemopathies, on 36 with tuberculosis, and on 17 with other diseases. Huggins' method of determining the iodoacetate index as related to the total protein content of serums was modified by the use of potassium cyanide, another inhibitor of the coagulation of serum proteins, instead of iodoacetate. The new reagent has the disadvantage of being unstable, but it does not cause ocular disturbances or dermatitis of the hands, as iodoacetate does. Negative results were obtained in the normal persons. A qualitative defect in the proteins of the serum was identified by the thermal coagulation tests in 69 (77.5%) of the patients with cancer, but normal results were obtained in 10 cancer patients (11.25%). Pathological results were obtained in 19 of the 36 patients with tuberculosis, in 42 of 77 patients with malignant diseases of the blood, and in seven of the 17 patients with other diseases. Thus the potassium cyanide test as well as Huggins' iodoacetate test is not a reliable biologic diagnostic method for cancer. This test can at best make exclusion of cancer possible, but not even that with certitude. For these reasons the authors believe that these tests should not be accepted as diagnostic methods, especially since the reagents used may cause untoward reactions, may be unstable, or may cause errors in interpretation.

18:367-508 (July-Aug.) 1950. **Partial Index**

*Acute Edema of Lung Due to Inhalation of Oxides of Nitrogen. G. Botelho.—p. 371.

Acute Edema of Lung Due to Oxides of Nitrogen.—This is a serious and frequent industrial accident. The commonest lesions are those in the respiratory tract, the type and clinical course of which depend on the particular oxide of nitrogen involved and its concentration, the duration of exposure, and the sensitivity of the victim. Prolonged exposure of workers to various oxides of nitrogen at low concentration causes chronic irritation of the respiratory tract with dyspnea and pain in one or both lungs. Later on, chronic bronchitis, bronchiectasis, emphysema, and bronchiolitis obliterans develop. The roentgen picture is similar to that of pulmonary miliary tuberculosis associated with dilatation of the right side of the heart. Exposure to these gases at higher concentrations causes vertigo with or without loss of consciousness, cough, asphyxia, and a burning sensation in the respiratory tract followed by pulmonary disorders, abundant expectoration of bright red blood, and, frequently, pulmonary edema. The pulmonary disorders may be controlled by treatment or may progress to acute pulmonary edema with death of the patient in one or three days. In rapidly fatal cases the only lesion is acute pulmonary edema. Poisoning of a shock type is due to inhalation of these gases at massive concentration. Death is due to stagnation of blood in the pulmonary vessels and cessation of respiration. The treatment consists of immediate removal of the patient from the contaminated atmosphere, inhalation of oxygen, daily intravenous injections of a dose of 100 or 200 cc. of a 50% hypertonic dextrose solution, and administration of penicillin and mersalyl. Codeine and barbital derivatives should be given as sedatives. Venesection is indicated in cases of acute pulmonary edema. The author reports good results from the aforementioned treatment in two cases of subacute poisoning.

*Nitrogen Mustard in Treatment of Psoriasis. J. Gómez Orbaneja.—p. 299.
*Modified Boschi's Treatment of Tetanus. C. Bravo Mateos.—p. 320.

Nitrogen Mustard in Psoriasis.—Gómez Orbaneja administered nitrogen mustard (tris-beta-chloroethylamine hydrochloride) to seven patients with psoriasis of various types and of long duration. The drug was given every other day, in doses of 2.5 mg. to adolescents and of 5 mg. to adults, up to a total of three or five injections. In most cases it was well tolerated. Some patients complained of asthenia, headache, nausea, and vomiting. In one of the patients mucosal lesions developed, which were controlled by blood transfusion. The patients were observed for five months after discontinuation of the treatment. In three patients, cure of skin lesions persisted five months after treatment. In four, apparent cure was followed by a recurrence within two or four months. The recurrent lesions were moderate in three patients and of the same severity as those prior to the treatment in one patient. The author states that nitrogen mustard is the only drug with constant favorable effects on psoriasis. Treatment should be given only to hospitalized patients in whom psoriasis cannot be controlled by topic treatment, since the drug may produce blood changes or other severe toxic effects.

Modified Boschi's Treatment of Tetanus.—Bravo Mateos' modification of Boschi's technique is as follows: (1) lumbar puncture with aspiration of the cerebrospinal fluid until no more fluid can be aspirated and (2) injection of 20 cc. of twice-distilled water through the same needle. One hour later blood serum (in doses not specified by the author) is given subcutaneously and glutealy. The treatment is repeated at intervals of 12 hr. for two or three consecutive days. After every treatment profuse perspiration occurs and great subjective improvement is observed. The author reports cure of four patients with tetanus with the use of this method.

*Herpes Zoster of Lower Extremity. A. Shedrow.—p. 271.
Congenital Toxoplasmosis. P. Klenerman.—p. 273.

Herpes Zoster of Lower Extremity.—Herpes zoster involving the lower extremities accounts for only 9% of all cases of this common disease. Three cases involving the lower extremities are reported, one of which had an associated varicella-like eruption. It is not known whether herpes zoster and varicella are caused by the same strain of virus or whether they are due to different strains of a similar virus. Although the same ganglions were involved in all three of the reported cases, the symptoms differed. It is apparent that a severe eruption may accompany a mild inflammatory process and vice versa. Herpes zoster may be symptomatic of pressure on the sensory ganglions, caused by an infiltrative lesion or a new growth such as leukemia or a lymphoblastic process, a tuberculous or syphilitic granuloma, or a metastatic malignant lesion. Latent leukemia should be excluded. Differential blood cell count should be done routinely in every case of herpes zoster. Many cases of this disease are overlooked, especially when the eruption is mild and not diffuse. It is not necessary for a thick outcropping of vesicles to be present before herpes can be diagnosed; a solitary erythematous patch with clinical symptoms is compatible with such a diagnosis.

Choledocholithiasis and Calculous Disease of Gallbladder: Differences Between the Two Conditions. R. Demel.—p. 265.
*Problem of Conglutinating Activity in Fetal and Infantile Serums. F. Seelich, P. Speiser and P. Elsner.—p. 267.
Toxoplasmosis. E. Cuboni.—p. 272.

Conglutinating Activity in Fetal and Infant Serums.—One hundred and eighty-six cord serums of newborn infants were tested for their ability to conglutinate Rh-positive erythrocytes containing incomplete antibodies. Results confirmed the observations by Wiener and Witebsky that serums of infants born prematurely show the lowest degree of conglutinating activity and that this activity increases with advancing age. Despite the slight conglutinating effect usually exerted by the serums of newborn infants, the serum of premature infants may occasionally be capable of eliciting in vitro clumping of blood cells moderately sensitized by incomplete antibodies. Adult serums were treated with an excess of sensitized cells in an attempt to extract the conglutinin from the serums and then to use these adult serums as diluent to determine the conglutinin titer of infant serums. However complete inactivation of adult serum could not be obtained either with an excess of sensitized cells or old serums with very low conglutinating activity. Adult serums with very little conglutinating activity were used as diluent for determination of the conglutinating titer of 90 serums of infants. The cord serums showed little conglutinating activity, with average titers of 1: 4.6 in infants between the ages of 2 and 14 days as compared to an average titer of 1: 19 in adults. It is of practical importance that in the presence of Rh-positive erythrocytes containing a small charge of incomplete antibodies, the conglutinating activity of fetal or of newborn infant serums will not always be sufficient to elicit conglutination. Thus transfusions in hemolytic disease of the newborn may be harmful because of the transfusion of conglutinin together with the erythrocytes of the adult blood. Both protein content and conglutinating activity of adult blood are unphysiological for the newborn infant. The authors believe that erythrocytes suspended in plasma diluted with sodium chloride solution to the average physiological protein level of newborn infants is best for exchange *transfusions.*

BOOK REVIEWS

The Physiology and Pathology of Hemostasis. By Armand J. Quick, Ph.D., M.D., Professor of Biochemistry, Marquette University School of Medicine, Milwaukee. Cloth. $4. Pp. 188, with 18 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1951.

This excellent manual serves to summarize much of the recent work in the rapidly expanding field of blood coagulation. Much of the work is a recapitulation of the author's recent publications in the field, a field in which he is an acknowledged authority. The style is good, and the format is excellent. The book suffers, unfortunately, from a lack of scientific detachment and objectivity in many of the presentations of controversial material, for example, the value of the two-stage prothrombin test, Ac globulin, and Owren's factor V. At times this is carried to a point where the text takes on the nature of a polemic, with but one side of the controversy being presented. The bibliography is excellent. The section on methods is extremely valuable, especially in the presentation of recently introduced techniques. It suffers from the exclusion of tests that the author does not consider worth including. There are only a few minor typographical errors, for example, in Tables X and XI. Within its limitations, the book serves a very useful purpose.

Pioneer Doctor. By Lewis J. Moorman, M.D. Cloth. $3.75. Pp. 252, with illustrations. University of Oklahoma Press, Norman, 1951.

This book tells of many incidents in the life of a physician who is genuinely interested in what he can do for the sick. Dr. Henry A. Christian points out, in the foreword, that it is such stories of medical practice that are needed today to counteract the fact that medicine has "become more mechanistic and less humanistic, more mechanical and less spiritual than in the past." Dr. Christian says there seems to be decreasing interest in man as a human being as he passes through a hospital regimen of technicians and tests, of apparatus and machines. Books like this one should be a balance against such tendencies. Dr. Moorman's professional life has been spent mostly in Oklahoma, where, at the beginning of the last century, he began the practice of medicine in frontier villages (Jet and Chickasha) among the rugged plainspeople whom he loved. The numerous humane stories from his practice are most interesting. After years of practice on the unplowed prairies, he went abroad for postgraduate study in the clinics of Vienna, then returned to Oklahoma City, where he became especially interested in the treatment and care of tuberculous patients. His knowledge gained in this special field is reviewed in several chapters in this book. Dr. Moorman was a teacher in the University of Oklahoma School of Medicine for many years and finally became dean of the school.

Medical Neuropathology. By I. Mark Scheinker, M.D., Assistant Professor of Neuropathology, University of Cincinnati College of Medicine, Cincinnati, Ohio. With foreword by Marion A. Blankenhorn, M.D., Professor of Medicine, University of Cincinnati College of Medicine. Cloth. $10. Pp. 372, with 186 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1951.

This is the third book on neuropathology which has been written by Dr. Scheinker in recent years. In this volume the author states that he has attempted to present neuropathology in its relation to internal medicine and general pathology. Much of the book is devoted to the relation of disturbances of the central nervous system to cardiovascular disease—184 of 345 pages. In this section the author emphasizes his impression of the importance of functional vascular disturbances: vasospasm, vasoparalysis, stasis, and thrombosis without disease of the vessel walls. Much of what the author has to say is controversial, but he does not supply sufficient factual data to permit the reader to evaluate his hypotheses. In fact, the entire book is characterized by its superficial treatment of the subject matter. In the remainder of the book the author discusses cerebral disorders due to exogenous toxins and blood dyscrasias and associated with diseases of the lung and liver, and neuritis.

The preparation of this book has not received the care of which the subject and the excellent job of printing are worthy. There are several misspelled words and names. Many of the articles cited in the text are not included in the bibliography. In a few instances the author's failure to mention modern developments is appalling. On page 346 where the etiology of kernicterus and icterus gravis neonatorum is discussed there is no mention of the Rh factor, and the most recent reference cited is dated 1935 but is not given in the bibliography. On page 287 where he discusses influenzal meningitis, the mortality is given as eighty-five to ninety-four per cent; no mention is made of the improvement obtained with modern chemotherapy and antibiotics. The most recent reference to the literature is dated 1922, and it is not to be found in the bibliography. There are a number of neurological disorders that are commonly associated with disturbances in other parts of the body which are not included in this book. Most noteworthy are meningococcic meningitis, the frequently associated meningococcemia and disturbance of the adrenals; the acute encephalitic disorders associated with vaccination and the acute infectious diseases (except pertussis), and parasitic infestations.

Biometric Analysis: An Introduction. By Alan E. Treloar, Ph.D., Professor, Division of Biostatistics, School of Public Health, University of Minnesota, Minneapolis. Paper. $4.50. Pp. 251, with illustrations. Burgess Publishing Company, 426 S. 6th St., Minneapolis 15, 1951.

The author of this book has undertaken the difficult task of setting forth, for graduate students in the biological and social sciences, the most essential principles of biometry. The primary objective has been to emphasize the reasoning behind the statistical methods. Readers who hope this book may provide a royal road to statistics will inevitably be disappointed. However, the book abounds in numerical examples from clinical and preventive medicine, and prospective authors of papers reporting therapeutic results would do well to read the section on the fourfold table on pages 231 to 237.

A number of subjects of great interest to medical readers are not represented in the index: the rank-difference method of estimating correlation, measurement of reliability and validity, Spearman's coefficient of correlation, self-correlation, test-retest methods, and the problem of scoring new tests. The author also confuses his reader by using the word "control" in different senses on pages 6 and 215. It is to be hoped that this semantically objectionable word will soon be replaced by something better. Aside from these criticisms the book is evidently written with great care; the author's style is commendably direct, and the general appearance of the book is attractive.

Die Chirurgie der Poliomyelitis. Von Dr.med. Helge Sjövall. Chirurgie in Einzeldarstellungen, Band 46. Cloth. 13.80 marks. Pp. 98, with 52 illustrations. Walter de Gruyter & Co., Genthiner Strasse 13, Berlin W 35, 1951.

This small monograph has two main divisions, the first dealing with over-all considerations and the second with special surgical phases. Although somewhat abbreviated, etiology, pathogenesis, serology and immunology have been presented well. Schematic presentations are concise and clear, and roentgenograms interspersed throughout the text amplify many of the postoperative results. An extensive alphabetically arranged bibliography is included. The book mainly is a résumé of many of the accepted methods previously described. It can be recommended as a reference work for anyone able to read German.

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

QUERIES AND MINOR NOTES

MASS BLOOD-GROUPING PROGRAM

To the Editor:—*A blood-typing program is being undertaken here under the sponsorship of the American Legion. Since the present cost of typing serum runs about 40 cents a person, we are seeking a cheaper source of serum. We are considering preparing serum from persons giving a marked reaction to regular commercial typing serum, this serum in turn to be used as typing serum. Please advise as to the feasibility of such a procedure. This typing program is to tie in with the civil defense program here.* *L. K. Williams, M.D., Mena, Ark.*

Answer.—A mass blood-grouping program would be difficult to justify if blood-grouping errors occurred with any frequency. Frequent errors have occurred when poor quality testing serums were employed; undoubtedly, it was the frequency of such errors that led to the establishment of minimum requirements for blood-grouping serums through the agency of the National Institutes of Health. Few institutions or organizations have the personnel and facilities for preparing serums whose quality will equal or exceed these minimum requirements. For most institutions, the simplest assurance of quality is the procurement of anti-A and anti-B blood-grouping serums from a laboratory licensed by the National Institutes of Health for preparation of this material. In contrast to the frequent errors that may be anticipated with poor quality testing serums, the use of high quality government-licensed and tested serums is a powerful assurance against error, particularly under the probably hurried conditions of a mass blood-grouping program. The physician should insist on the use of high quality serums as a sine qua non for the contemplated program and should not allow himself to be misled by considerations of pseudoeconomy.

A tentative plan, for mass blood typing and a report on the typing program of Jackson, Michigan appears in the *American Journal of Clinical Pathology*, V. 21 #4 pp. 375 and 387, April, 1951.

MONGOLISM

To the Editor:—*A girl, 5, was referred to me for neurological evaluation. She had almost all the stigmas of mongolism, as described by C. E. Benda; she also had strabismus, nystagmus, and congenital bilateral deafness. Her twin brother is normal physically and precocious mentally. Is it not unusual for mongolism to be associated with congenital deafness and a normal twin sibling?*

Frederick P. Pokrass, M.D., Reading, Pa.

Answer.—Mongolism is almost always present in one twin only if the twins are dizygotic (dissimilar). There are only about six cases known where dizygotic twins were both affected with mongolism. Homozygotic twins are said to be always affected with mongolism concordantly. In the case under discussion, the normal twin brother may therefore be expected to be a perfectly normal child. Congenital deafness is rare in mongolism. Since many persons with mongolism who would have died in previous years are now surviving, we may see various congenital anomalies more frequently than have been observed previously.

CHOREA MINOR

To the Editor:—*I will appreciate authoritative advice as to the role of antibiotics and cortisone in chorea minor.*

Walter Newman, M.D., Springfield, Mass.

Answer.—There is no evidence that antibiotics or sulfonamides influence the course of chorea minor. From the evidence available at this time, the same may be said of cortisone and pituitary adrenocorticotropic hormone (ACTH).

ERYTHROBLASTOTIC BABY

To the Editor:—*A 22 year old multipara is pregnant. She is Rh negative, and her husband is Rh positive. Roentgenographic examination has shown a twin pregnancy. Her first and third babies, aged 4 and 2 years, are living and well. The second baby died six days after birth. The third child was jaundiced and pale at birth. The patient has had several abortions and has an Rh antibody titer, negative saline agglutinins and positive conglutinins through 1:320 dilution. Is there enough evidence at this time to decide that these fetuses are erythroblastotic and that they will require exchange transfusions immediately after birth even though they may not be jaundiced, edematous or anemic at that time? What is a significant level of saline and conglutinin Rh antibody titer? Can you describe the technique of exchange transfusions through the umbilical vein, with the use of silicon-coated tubing or catheters? I would appreciate other suggestions in regard to the management of this case?*

R. O. Chambers, M.D., Glendive, Mont.

Answer.—The clinical history and serologic findings indicate that one is dealing with a pregnant Rh-negative woman who is sensitized to the Rh factor and is therefore apt to have an erythroblastotic baby. The prognosis depends primarily on the Rh type of the fetus. Therefore, the husband should have more complete Rh-Hr tests, and the blood of the two living children should be typed as well as the blood of the husband's parents, if available, to determine, if possible, whether the husband is homozygous or heterozygous. If the husband is homozygous, the expected baby will be Rh positive and therefore almost surely erythroblastotic; if the husband is heterozygous, there is a 50 per cent chance that the baby will be Rh negative, in which case the maternal Rh antibodies cannot harm it. One must bear in mind that, while identical twins always have the same blood type, in the case of fraternal twins one may be Rh positive and the other Rh negative.

The severity of the illness in the fetus or baby depends primarily on the height and duration of presence of the maternal antibody titer, though there are other factors that also appear to play a role. The Rh antibodies are of two main varieties: agglutinating antibodies, which clump Rh-positive cells in saline as well as in other mediums, and conglutinating antibodies (univalent, blocking or "incomplete" antibodies), which do not clump positive cells in saline mediums but do clump cells in plasma, albumin and similar mediums. It is only the latter type of antibodies that traverses the placental barrier and is clinically significant. Since a number of tests of different sensitivities have been devised to detect univalent Rh antibodies, the report of antibody titer should specify the method used. For example, a serum with a titer of only 1 unit by the blocking method would have a titer of about 20 to 40 units by the conglutination method, 40 to 80 units by the antiglobulin method and 100 to 200 units in tests with enzyme-treated cells. If the antibodies are so weak that they can be demonstrated only in tests with enzyme-treated cells or by the antiglobulin method, the manifestations in the Rh-positive baby are apt to be mild or subclinical. On the other hand, if the antibodies are so strong that the blocking test is distinctly positive, then there may be about a 50 per cent chance that the Rh-positive fetus will be stillborn. The outcome in cases with titers of intermediate values is roughly correlated with the height of the antibody titer, but it is not absolutely predictable because other factors play an important role, especially the manner in which the case is managed. When the baby is born, its blood should be typed. If the baby is Rh positive, and the mother had a significant level of univalent Rh antibodies antenatally, the baby will almost surely be erythroblastotic, and it is justifiable to proceed with an exchange transfusion on these findings alone. Many workers prefer to perform tests to determine whether the baby is clinically ill with

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

erythroblastosis before proceeding with the exchange transfusion. For this purpose the hemoglobin concentration, icterus index of the cord serum and tests for coating of the baby's red cells by Rh antibodies (antiglobulin, or Coombs test, and conglutination test) are most helpful.

For the technique of performing exchange transfusion, one may refer to the papers by Wallerstein (The Treatment of Erythroblastosis Fetalis by Substitution Transfusion, *Blood,* Spec. Issue no. 2, p. 170, [Jan.] 1948), Wiener and Wexler (Erythroblastosis Fetalis: Method of Wiener and Wexler in Conn, H. F.: Current Therapy, Philadelphia, W. B. Saunders Company, 1950, pp. 160-162, and Brancato (Exchange Transfusion in Erythroblastosis Fetalis and Other Conditions, *Am. J. Dis. Child.* **80:**1 [July] 1950).

BRONCHIECTASIS

To the Editor:—*A 28 year old man has had bronchiectasis for 20 years. Operation was refused. An x-ray of the left dome of the diaphragm is irregular and shows limited motion. The hilar shadows are thickened and show dilated bronchioles. Staphylococcus albus and Escherichia coli are present in the sputum. Spasmodics have been given and creosote oil by postural inhalation. Aureomycin was given for two weeks. After a rest period, chloramphenicol was given. After another rest period, sulfamerazine was given for three days. There is some improvement. After each postural treatment the patient eliminates ½ glass of pus. The ausculatory sounds are improving in the apexes of both lungs. What antibiotics are advisable?*

Jacob Aisenstat, M.D., New York.

Answer.—It seems unfortunate that operation was refused by this patient. It appears that he is suffering from bronchiectasis of the left lower lobe. At best, the therapeutic use of sulfonamides or antibiotics in this patient can be considered only as a palliative measure, from which lasting improvement cannot be expected. While it might be possible, through the continued use of aureomycin, chloramphenicol or terramycin, to so suppress the infection that for a time considerable improvement in the patient's general condition would occur, such a procedure would have its dangers. There is an increasing number of reports, such as that of Woods and co-workers (*J. A. M. A.* **145:** 207 [Jan. 27] 1951), which definitely indicate that care must be taken when the newer antibiotics are being employed so that a superinfection with yeastlike organisms that are resistant to chemotherapy and antibiotic therapy does not occur. Pulmonary moniliasis has developed in patients receiving one or the other of the newer antibiotics for the treatment of bronchiectasis. Because of these observations, it would seem best that the patient described should be treated with sulfadiazine or an antibiotic such as aureomycin, terramycin or chloramphenicol, only for the control of an acute exacerbation or spread of bronchiectatic lesions. In adults, treatment with 2 to 3 Gm. per day of the chosen antibiotic, for seven to 10 days, will assist in controlling the exacerbation or spread of the infection. Conservative measures, such as bed rest and postural drainage, should be used while the antibiotic or sulfonamide is being given.

MEASLES WITHOUT A RASH

To the Editor:—*I have seen a number of cases in recent epidemics which have a typical clinical picture of measles except for the rash. Am I justified in stating that such persons have had measles?*

M.D., New Jersey.

Answer.—Sometimes physicians assert that they have seen measles patients without a rash. Usually such observations are difficult to substantiate and yet they actually seem to occur in rare instances. When immune globulin is used for prevention there should be no rash. When measles is modified by immune globulin, an eruption is to be expected, but its intensity and duration may be greatly diminished. The only justification for asserting that a patient had measles without a rash would be the failure of such a patient to contract the disease when exposed to an early case of measles. Twenty-five years ago Tunnicliff and Taylor (*J. A. M. A.* **87:**846 [Sept. 11] 1926) reported a skin test for susceptibility to measles; however, the method is no longer in use.

FLUSHING OF FACE AND EARS

To the Editor:—*I have been treating a dentist, 48, who for the past 10 years has had attacks of severe flushing of face and ears, more prevalent in the winter and on changes of temperature. He feels as if he were "grippy," with lethargy and weakness of thighs but no fever or pulse changes. The attacks last for one-half hour to several hours and disappear spontaneously, with face and ears resuming their natural color. These attacks closely resemble climacteric symptoms of women. Except for a labile type of blood pressure, the physical and laboratory findings are within normal limits. I have diagnosed the condition as vasomotor instability. I would appreciate your opinion.*

M.D., New York.

Answer.—Attacks of flushing of the face and ears belong to a group of vasodilator phenomena that may be of central or peripheral origin. The so-called diencephalic syndrome is accompanied by flushing of the face and neck, together with a rise in blood pressure. It may be precipitated by a small dose of subcutaneously administered histamine. On the other hand, it may represent a biphasic reaction of an initial vasoconstriction, with pallor and profuse sweating and should be tested with piperoxan hydrochloride (benzodioxan), so that pheochromocytoma may be ruled out. A small irritative lesion near the vasodilator center may have to be considered. Nothing is said about salivation and lacrimation during attacks. Local vasodilater phenomena may occur as a result of previous exposure to cold or sunlight, which results in a hypersensitive state. In addition to physical allergies to cold and light, one must consider drug sensitivity to procaine in a dentist, which, of course, would most probably affect his hands but may as a result of some localizing factor result in vasodilation and increased permeability on the face. If the pressure falls during such attacks then an allergic mechanism is more likely. The feeling of lethargy and weakness of the thighs may indicate cerebral vasodilation or edema. Nothing has been said about headache during the attack, the presence of which would then classify this as a case of erythralgia of the head, which often responds to desensitizing doses of histamine.

Such a patient requires intensive study in a hospital under personal observation of a physician specializing in neurovascular phenomena. It may be a harmless but intractable symptom; it may be a tumor of the third ventricle. Polycythemia must be ruled out even if the hemoglobin and the blood cell count are within normal limits.

ANOSMIA

To the Editor:—*What can be done for a 50 year old woman who has almost complete loss of taste and partial loss of smell? She can distinguish only sweet, sour, bitter and salt. This condition followed an acute upper respiratory infection one year ago, when she received four injections of penicillin.*

Earl M. Slagh, M.D., Elsie, Mich.

Answer.—Anosmia, or loss of the sense of smell, is a symptom rather than a disease. In general, for the normal perception of odors three factors are essential: 1. It must be possible for the odoriferous particles to come in contact with the olfactory region of the nose. 2. The mucous membrane must be moist and in a healthy condition. 3. The olfactory terminals and their nerve tracts must be normal. It will be seen that interference with the sense of olfaction may therefore be (*a*) of an intranasal or (*b*) of an intracranial character. The loss of taste complained of by the patient is due to the abeyance of the perception of flavor, which depends on the sense of smell.

If the anosmia is due to an obstruction, a foreign body or any one of many intranasal conditions that prevent air from reaching the olfactory region, surgery, to relieve obstruction and to permit the air to reach the olfactory region, may effect a cure. If, on the other hand, the nerve endings in the olfactory mucous membranes have been damaged from atrophic rhinitis or any irritant, the likelihood of relief is minimal. If the cause of the anosmia is intracranial, the prognosis is hopeless. Hysterical anosmia does occur from time to time; this form is treated chiefly by suggestion.

CARBON DIOXIDE TREATMENT OF PSYCHONEUROTICS

To the Editor:—*An article in* Time *several months back reports that Dr. Meduna has had some success in treating pyschoneuroses through giving inhalations of carbon dioxide. Being a stutterer, I am interested in the matter.*

Robert E. Longacre, M.D., Mexico, D. F.

Answer.—The carbon dioxide therapy consists of repeated inhalations of a gas mixture containing 30 per cent carbon dioxide and 70 per cent oxygen. The average number of respirations administered at each treatment is about 35. The number of treatments varies greatly from case to case, the range being between 30 and 120 treatments. The treatments are usually given three times a week on alternate days. All psychoneurotic and psychosomatic disorders may improve with the treatment, with the exception of obsessive compulsive neuroses and psychotic conditions. Dr. L. J. Meduna, of the University of Illinois has written a monograph dealing with the carbon dioxide treatment (Carbon Dioxide Therapy—A Neurophysiological Treatment of Nervous Diseases, Springfield, Ill., Charles C Thomas, Publisher). He reported on 33 stutterers who finished the course of treatment. Eleven of these achieved 100 per cent improvement; three patients achieved better than 75 per cent improvement; two patients achieved 50 per cent improvement and five patients achieved 25 per cent improvement. That would mean 11 cures and 10 improvements out of the group of 33.

Dr. Kindwall, Milwaukee, reported about 50 per cent improvement in a group of 70 psychoneurotic patients with diverse conditions. Reports on the carbon dioxide treatment were favorably received by the First International Congress of Psychiatry, held in Paris in October 1950.

FIVE PER CENT HUMIDITY

To the Editor:—*I am the plant doctor for a corporation which will soon put quite a few men to work where the humidity will be limited to 5%. Have you information on how to adjust the salt and water intake for these men while working?*

Howard P. Sloan, M.D., Bloomington, Ill.

Answer.—Among healthy workers, thirst alone is a sufficient guide to water intake, provided adequate salt entry is accomplished. On a practical basis one standard salt tablet (slowly disintegrating type preferred) with every substantial drink of water is enough. In a few portions of the country, at least seasonally, the outside air provides only 5% relative humidity. This state is to the delight of most exposed persons otherwise comfortably situated. In extreme cold weather in houses heated by hot air, a 5% humidity is not extraordinary. In both circumstances complaints that arise concern skin and mucous membrane dryness and cracking, and difficulty in keeping warm even when dry bulb thermometers register high. High altitude adds to discomfort due to cold when one is not in sunshine. This query fails to note the prospective temperature, the degree of air motion, and the extent of physical labor, all of which are important considerations. The foremost trouble, notably in hot summer weather, may appear on passing from the artificial workroom climate to the natural outside state. Metabolic adjustments quickly imposed may induce "weather shock." The maintenance of 5% humidity in the presence of varying temperatures is desirable in keeping with outside weather.

FRIGIDITY

To the Editor:—*What therapy should I use for a patient who is under nervous tension during intercourse with her husband? She cannot relax and reach orgasm. Would male hormone help?*

M.D., New York.

Answer.—The male hormone is of considerable help to some frigid women, but it does not always relax nervous tension. One may try giving 20 mg. of testosterone propionate hypodermically three times a week for four weeks, or a 5 mg. buccal tablet of testosterone twice a day for 20 days. If the male hormone therapy does not help, the patient should have psychotherapy, preferably by a trained psychiatrist.

CHLORINATED WATER

To the Editor:—*What studies have been made to determine the deleterious effects of heavily chlorinated water that is used for drinking purposes? The water supply in our town is chlorinated but not filtered. At times it is possible to smell the chlorine. Could this harm the gastrointestinal or the genitourinary tract? William J. Llewellyn, M.D., Nicholson, Pa.*

Answer.—A search of the literature did not reveal any organized investigations on the problem of the effect of heavily chlorinated water on the human body. Allergic manifestations of chlorinated water have been reported. Many cases of asthma have been traced to an allergy to chlorinated water (Watson and Kibler: *J. Allergy* 5:197, 1933; Bohen: *J. Allergy* 5:199, 1933; and Sheldon and Lovell: *Am. Pract.* 4:43 [Sept.] 1949). In all these cases the asthma was relieved or disappeared when the patient drank distilled or unchlorinated water.

Sensitivity to greater concentrations of chlorine and chlorine compounds than are usually found in drinking water has been reported. Cases of sensitivity to sodium chloride (Guttman: *J. Allergy* **15**:395, 1944) have been reported. Cases of allergic dermatitis caused by dilute solutions of sodium hypochlorite have been reported (Urbach and Gottlieb: Allergy, ed. 2, New York, Grune and Stratton, 1946, p. 404).

ACTH, CORTISONE AND HEMORRHAGIC TENDENCIES

To the Editor:—*Please let me know whether there are any reports available on hemorrhagic tendencies from the use of cortisone.*

M.D., New York.

Answer.—Thus far there has been considerable speculation and some suggestive experiments, but little specific evidence to show that increased hemorrhagic tendencies develop with the use of pituitary adrenocorticotropic hormone (ACTH) and cortisone. There is some evidence that they may actually produce hypercoagulability of the blood and a beneficial effect on purpuras of allergic origin has been observed. Adrenal cortex hormones generally exercise a capillary stabilizing effect in the presence of a variety of stress stimuli. Proper precautions in their use should be observed, since there have been reports of gastrointestinal bleeding during the administration of cortisone and ACTH, presumably due to active bleeding ulcers that have developed or reactivated ulcers. Their use is therefore contraindicated in patients with a history of an active or previously active bleeding peptic ulcer. Also, patients with Cushing's syndrome, a type of hyperadrenocorticism, often exhibit easy bruisability. A similar state of adrenal overactivity may occur with prolonged use or high dosages of ACTH or cortisone.

EXTERNAL OTITIS

To the Editor:—*My 14 year old daughter has had bilateral external otitis. Cultures show a pure growth of Bacillus pyocyaneus. I tried local instillations of terramycin and am now trying streptomycin, to which the organism is sensitive in vitro. The results are somewhat encouraging, in that the edema and pain are subsiding, but the cultures are still positive. Any recommendations as to treatment will be appreciated.*

M.D., New York.

Answer.—Bacillus pyocyaneus is one of the most frequent causes for chronic external otitis infections. Most cases respond to cleanliness and to the local use of tincture of thimerosal 1 to 1,000 or 2 per cent aqueous methylrosaniline chloride (gentian violet). Recently aureomycin powder has been used with excellent results. One should carefully clean the ear and then blow in the powder gently, leaving only a small amount in the ear. A larger amount tends to cake and is difficult to remove. Aureomycin otic solution may be used instead of the powder. Local sensitization to any medication is apt to occur, so that it may be necessary to change to another type of medication if the infection does not clear up promptly. Where the infection is stubborn and tends to recur, an attic cholesteatoma should be looked for.

FIBROSITIS AND WEATHER VARIATIONS

To the Editor:—*Four years ago, I began to have seasonal hay fever (from the middle of May to the first of September), which has not responded to treatment by allergists. Three years ago, chronic lumbago, right sacroiliac neuritis, and fibrositis of the cervical vertebrae developed; they give me trouble in the winter but go away during hot weather. X-rays and examinations by orthopedic specialists are negative. All tests and examinations, otherwise, are negative. I am 41 years old and feel pretty good except for chronic fatigue. Is there any connection between the hay fever and fibrositis? Why does fibrositis improve in warm weather? I have not tried cortisone or ACTH. What treatment would you advise?*

M.D., Georgia.

Answer.—Studies of fibrositis have thus far failed to disclose any relationship to clinical forms of allergy, such as hay fever, asthma, urticaria, and angioneurotic edema. Desensitization procedures and limitation of dietary intake of foods that give positive results in skin tests have failed to relieve fibrositis. Antiallergic pharmaceutical preparations do not provide relief of fibrositis in usual cases. Histamine desensitization, epinephrine, ephedrine, and antihistaminic drugs have been tested and discarded.

Discovery of the therapeutic effects of cortisone and pituitary adrenocorticotropic hormone in rheumatoid arthritis has led to study of patients with rheumatic diseases, with a view to determining whether adrenocorticotropic insufficiency is present in those conditions. Available information at present indicates that no such insufficiency is present in rheumatoid arthritis, osteoarthritis, or fibrositis.

Relationships between symptoms of fibrositis and weather variations have been studied. There seems little doubt that a relationship exists, in that many patients with fibrositis note symptomatic aggravation in times of rapidly changing weather. Factors examined included temperature, humidity, barometric pressure, and atmospheric electricity. Only barometric pressure variations have shown any close association with changing symptoms. Other factors do not seem to play a part. It is worth noting that alterations in relation to weather are purely subjective; there does not appear to be an acceleration or diminution of organic tissue lesions in association with weather changes.

Studies of therapeutic application of cortisone and pituitary adrenocorticotropic hormone have not progressed to a point where it is possible to recommend their use in fibrositis. One should consider that this condition is fundamentally benign and devoid of crippling effects and that present day use of these hormones is expensive and to some extent dangerous. Further study of this point is desirable, but at present, it seems advisable to employ more conservative therapeutic measures. Treatment measures currently in use for fibrositis include regulated periods of rest and intensive local physical therapy in the form of baking, hot applications, massages, and exercises. Infected foci should be removed on general principles. Use of analgesic drugs, such as acetylsalicylic acid, is helpful for relief of pain, and sedatives, such as phenobarbital, often help such patients to obtain restful sleep.

WINE HABITUÉS

To the Editor:—*What is the difference between so-called winos and other types of chronic alcoholism? In my experience, the "winos" have been much more difficult to treat.*

Car. B. Cone, M.D., Vancouver, Wash.

Answer.—"Winos" are usually considered to be "skid row" type persons who drink cheap wine usually containing, according to some scientists, a quantity of fusel oil. For the most part these persons are both mentally and physically deteriorated when they reach the "row" stage. They continue on in "skid row," are taken to jail or a chronic psychiatric hospital, or end in the morgue. Owing to the physical and psychiatric changes, most approaches have not been helpful (medical, medical-psychological, lay group and spiritual or moral). The "winos" are more difficult to treat because of their low level philosophy and sick mentation acquired rather early and found many times even in the temporary "skid row" younger inhabitant. The treatment is further complicated by the fact that nearly all "winos" drink, sip or "slug" wine into their bodies continuously, without taking in food of any kind, thereby again complicating the treatment by the presence of food deficiency effects on their physical and neurological systems.

WHISKY FOR PERSONS WITH "STROKES"

To the Editor:—*What effect has alcohol (whisky) on cerebral blood flow? Should it be recommended for persons with strokes?*

G. L. Lester, M.D., Chautauqua, N. Y.

Answer.—C. B. Thomas (*Arch. Neurol & Psychiat.* 38:321, 1937) states that alcohol causes a dilatation of the cerebral blood vessels. Stanley Cobb (*A. Res. Nerv. & Ment. Dis. Proc.*18:719, 1938) believes that alcohol causes dilatation of the cerebral vessels and that many patients with cerebral vascular disease show improvement with the daily ingestion of small quantities of alcoholic beverages. Even if it does not improve the cerebral circulation or the neurological state of these persons, it may render their lives more tolerable and therefore be distinctly worthwhile.

INFANTILE DIARRHEA

To the Editor:—*In a reply to a query in* The Journal *on the oral therapy of diarrhea* (**146**:*416 [May 26] 1951) your authority states that administration of 5% dextrose solution given orally would not be wise because of the resulting increased fermentation. This drawback is not regarded as valid for rice water, which is thought to pass so quickly along the gastrointestinal tract that fermentation is not increased.*

The theory that there are unfavorable results from the administration of carbohydrates in diarrhea was originally proposed by Finkelstein and was the basis for his well-known protein milk. However, in subsequent years, even Finkelstein himself was convinced that this concept was erroneous, and in later writings he freely advocated the addition of sugar to protein milk in cases of diarrhea. The general experience in this country in the past quarter of a century has supported Finkelstein's later views that the administration of carbohydrate is helpful rather than harmful in these cases. Although some degree of fermentation of unabsorbed carbohydrate may occur in digestive disorders, it would appear that the fermentation only affects that fraction of the carbohydrate, which cannot under these circumstances be assimilated. The products of fermentation, once thought to be irritating and to aggravate the diarrhea, appear to be harmless in that respect.

BISHYDROXYCOUMARIN AND MYOCARDIAL INFARCTION

To the Editor:—*In* The Journal, *May 12, in Queries and Minor Notes I read with great interest your answer to the question on anticoagulant therapy "Should every patient with myocardial infarction receive dicumarol® for the rest of his life?" I concur with your answer, and should like to add our own experience with anticoagulant therapy.*

We have studied a series of 150 patients with myocardial infarction. Half of them receive bishydroxycoumarin (dicumarol®) in addition to the usual therapy. No appreciable difference in mortality was noted between those patients who received the drug and those who did not. Bishydroxycoumarin increases materially the per capita cost and in some instances added many anxious days. We believe that the rather impressive favorable statistics reported by some clinicians may have been due to effective suggestive therapy, which accompanied the medical attention given to all patients receiving anticoagulant therapy. Bishydroxycoumarin or other anticoagulants are of distinct value and indicated only in cases of myocardial infarction complicated by thromboembolic phenomena.

AURICULAR FIBRILLATION

In past decades, many of the ablest medical investigators have attempted to resolve the mechanism of auricular fibrillation, the most important disturbance of the human heartbeat. The inconclusive nature of the results obtained by these workers undoubtedly is attributable to the fact that they did not utilize direct methods and their tools were not sufficiently sensitive to analyze the complex activity in the fibrillating auricles. For example, it it understandable that Sir James MacKenzie could not resolve the complex mechanism of auricular fibrillation from observations based solely on crude pulse tracings. The various earlier hypotheses were largely abandoned in 1920 when Sir Thomas Lewis, after extensive experimentation, advanced the circus movement theory. In the present investigation, the fibrillating auricle in man and animals has been reexamined with techniques not previously employed and apparatus not hitherto available. By these new methods the circus movement theory of auricular fibrillation has been found invalid, and the nature of the events in the fibrillating auricles elucidated.

Among the earliest hypotheses was that suggested in 1874 by Aubert and Dehn[1] and later supported by Kronecker and Schmey[2]; these workers believed that fibrillation was produced by injury to a nervous "coordination center" in the heart. In 1887, McWilliam[3] observed that spontaneous recovery from the arrhythmia often occurs in the dog. McWilliam offered the alternative concept that the fibrillatory wave pursues a sinuous path through the auricles, reentering its original pathway on completion of its course. In 1895, Englemann[4] advanced the theory of polytopic impulse formation, which gained the support of leading contemporary workers, including Lewis[5] and Winterberg,[6] until it was abandoned in favor of the circus movement theory. Mackenzie[7] in 1913 suggested that the auriculoventricular node was the cardiac pacemaker in the fibrillating auricle; he termed the arrhythmia "auriculoventricular nodal rhythm." The concept of tachysystole or a rapid tachycardia originating from a single ectopic focus was derived by Rothberger and Winterberg[8] in 1914 from the first investigation of auricular flutter and fibrillation by means of direct auricular leads.

Although the reentry concept of McWilliam, the intramuscular block experiments of Porter,[9] and the writings of Garrey[10] provided a basis for the circus movement theory, the widespread acceptance accorded this concept may be attributed to the investigations of Lewis and co-workers.[11] From a three year experimental study consisting primarily of an analysis of curves derived from direct auricular leads, Lewis concluded that auricular fibrillation is due to a single excitation wave traveling in a generally circular but variable and sinuous pathway through the auricles around the venae cavae. Reentry of the main wave into the circus pathway and the occurrence of centrifugal daughter waves arising from the main wave were postulated. The action of antifibrillary drugs was attributed to the supposed ability of these agents to eliminate the "excitable gap" on the circus pathway and thus to terminate the arrhythmia.

As Lewis himself recognized, the evidence provided by his study did not conclusively prove the circus movement theory. Because of the inadequate exposure of the heart used in his experiments, no observations could be made on the course of the excitation wave through the body of the left auricle. Because of the complexity and rapidity of the arrhythmia coupled with the relative insensitivity of the electrocardiographic equipment available, Lewis found that "anything like a complete analysis of the paths taken by the (fibrillation) waves becomes impossible."[11] Finally, most of the evidence supporting the circus move-

ment theory was derived from observations on experimentally produced auricular flutter; the occurrence of a circus movement in either experimental or clinical auricular fibrillation was largely assumed by analogy. Despite the absence of conclusive evidence, Lewis's circus movement concept is considered as established fact in the majority of standard textbooks discussing the mechanism of auricular fibrillation and at present is generally accepted by pharmacologists as the explanation for the antifibrillary action of various drugs.[12]

During the 30 years since Lewis' studies, a number of observers have reported findings which appear incompatible with the original circus movement theory, but none has succeeded in disproving the theory and none has provided direct and convincing evidence in support of an alternative hypothesis.[13] The inability of these workers to obtain conclusive proof concerning the mechanism of auricular fibrillation can be attributed to the limitations of the equipment and experimental methods at their command. Despite the technical advances of the late nineteenth and twentieth centuries, neither Lewis nor any previous or subsequent worker has been able to determine by direct observation precisely what occurs in the auricle during normal sinus rhythm or any auricular arrhythmia. In view of this circumstance, coupled with the fact that observations of the human auricles are few and relatively crude, an extensive study of the auricular arrhythmias was undertaken in our laboratory. During a four year period, modern apparatus was employed to investigate normal sinus rhythm and the four auricular arrhythmias in man and experimental animal.[14] The following report is a summary of the methods used and results obtained in the investigation of auricular fibrillation.

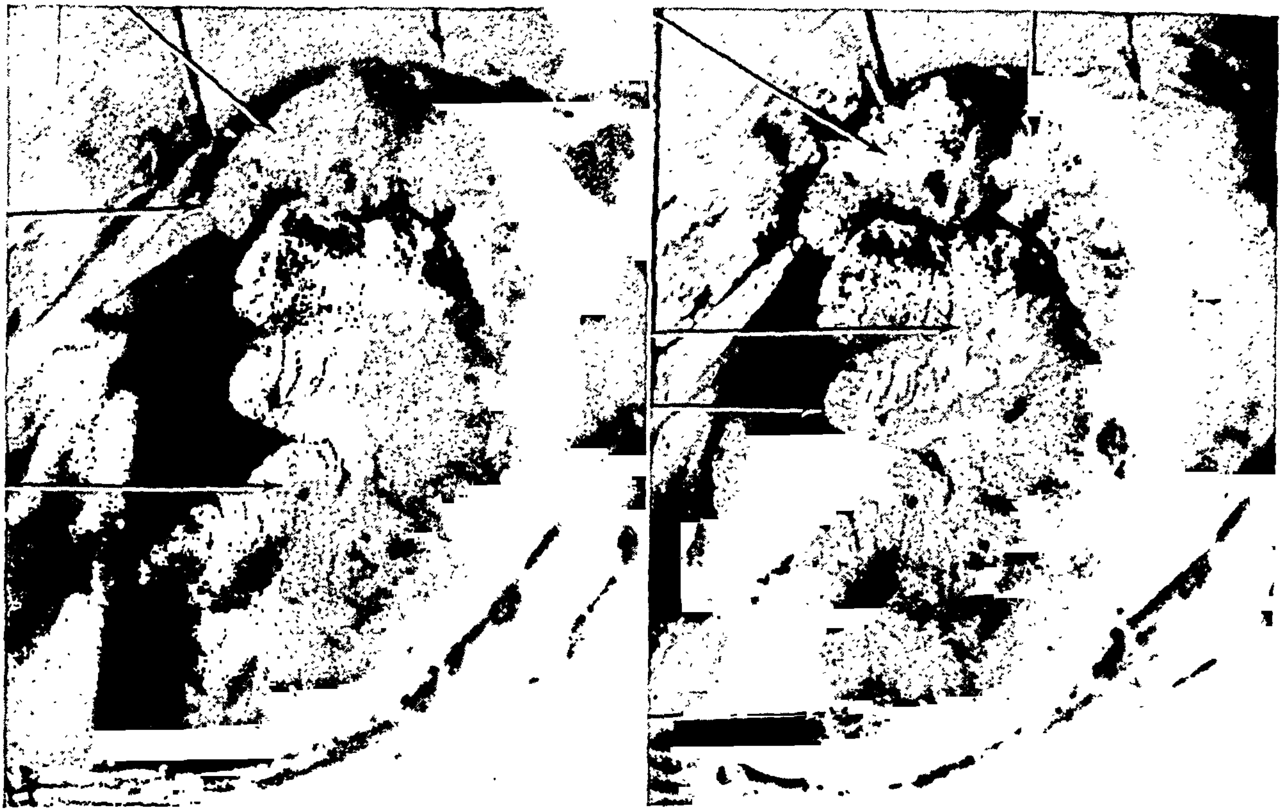

Fig. 1.—Left auricular appendix in a patient with mitral stenosis, auricular fibrillation, and congestive failure photographed just before the appendix was amputated for multiple emboli. There is a constant changing of the silhouette and surface configuration, which can be seen only in the motion pictures. Arrows point to small contractions. No circus movement is apparent.

EQUIPMENT AND METHODS

Many of the early investigations of auricular fibrillation were carried out before the electrocardiograph was available, while more recent studies have been based entirely on electrocardiographic interpretation. In the present investigation, the vast majority of observations in both man and animal were made by means of two recently developed instruments—the high speed cinematograph and the cathode ray oscillograph.

High speed color cinematographs of the fibrillating auricle in two patients were recorded during exposure of the heart for surgical removal of the auricular appendix. Experimentally produced auricular fibrillation in over 50 dogs was visualized in cinematographs of each auricle, of both auricles simultaneously, and of an area of the auricle approximately 1 cm. square photographed under high magnification. Identical equipment and photographic techniques were used in man and animal except for minor modifications designed to protect the patient. In pictures taken at 3,000 frames per second, the motion of the heart was slowed approximately 200 times when projected at 16 frames per second. The passage of a contraction wave could be clearly seen and studied. Even the minutest details of the rapid muscular movements in the fibrillating auricle were clearly demonstrated in the cinematographs for the first time. In our opinion, this visual evidence of the mechanism of auricular fibrillation is the most direct and most convincing reported to date.

The DuMont 279 dual beam cathode ray oscillograph was utilized to record multiple esophageal and limb leads in 24 patients with spontaneous auricular fibrillation. Single and simultaneous unipolar direct auricular lead oscillograms of the arrhythmia were obtained in 35 experimental animals. The oscillograph, an electronic device used with a preamplifier and camera, was resorted to after preliminary studies with various types of electrocardiographic equipment failed to yield a valid basis for conclusions concerning the mechanism of auricular fibrillation in either man or dog. Because of insufficient amplification and frequency response, mechanical inertia, and relatively slow maximum paper speeds, even the most advanced electrocardiographic machinery now available is incapable of accurately recording the rapid electrical activity in the fibrillating auricle. Among the advantages presented by the oscillograph are virtually unlimited amplification and frequency response, freedom from inertia, a recording speed 30 times greater, and a useful magnification several thousand times greater than that provided by standard electrocardiographic equipment.

The dogs used in the experiments generally were large, weighing 20 to 25 Kg. Morphine followed by intravenous administration of urethane in 25% solution proved most efficacious as an anesthetic. Artificial respiration was carried on through an intratracheal cannula. Early in the study, a relatively nontraumatizing operative technique was devised that permits complete exposure of both the right and left auricles. Thus the activity in all portions of the fibrillating auricles, including the hitherto unexplored body of the left auricle, could be observed in the cinematographs and direct lead oscillograms. The chief methods employed to produce auricular fibrillation were electrical stimulation and local application of aconitine.

MOTION OF THE FIBRILLATING AURICLE

In all essential respects, the cinematographic appearance of the fibrillating auricle is similar in man and in the experimental animal.

Cinematographic Appearance of Clinical Auricular Fibrillation.—When the auricles were observed in cinematographs of normal sinus rhythm, experimentally produced auricular premature systoles, paroxysmal tachycardia, and flutter, an orderly sequence of events was apparent: In each instance, alternating contraction and relaxation waves were seen to arise at a specific site on the auricle (the waves of normal sinus rhythm at the sinoauricular node, the waves of each arrhythmia at a single ectopic focus) from which they spread outward through the contractile auricular musculature in all available directions simultaneously. No such coordinated muscular activity occurs in clinical auricular fibrillation. Instead, cinematographs of the spontaneously fibrillating auricle in human subjects reveal the constant presence of a multitude of minute contractions and dilatations occurring asynchronously throughout all portions of the auricles except the noncontractile body of the left auricle and differing from any cardiac state previously described. Because of the rapidity and heterorhythmicity of the contractions, the silhouette and surface configuration of the auricles are constantly changing. Observers have compared the cinematographic appearance of the fibrillating auricle to a pot of boiling water or myriads of shimmering, reflected lights. Unfortunately, this effect of constant motion is largely lost in the still photograph shown in figure 1. No evidence of a circus movement, centrifugal daughter waves, or an "excitable gap" is seen in the fibrillating auricle of man.

The Cinematographic Appearance of Experimentally Produced Auricular Fibrillation.—Detailed study of cinematographs from experimental animals shows that the chaotic activity in the fibrillating auricle ranges from heterorhythmic contractions and dilatations of microscopic muscle segments to relatively rhythmic contraction and relaxation waves which travel measurable distances along variable pathways over the shimmering surface of the auricle (fig. 2). For purposes of description, these two orders of activity have been termed "M" or microscopic and "L," large or macroscopic activity. Both "M" and "L" activity occur simultaneously throughout all contractile portions of the auricular musculature.

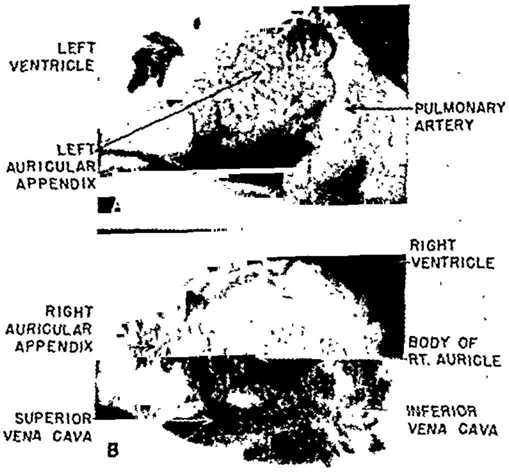

Fig. 2.—Still photographs from motion pictures of auricular fibrillation of (*A*) the left and (*B*) the right auricles in the dog. The numerous minute ("M") contractions are most prominent in the appendices.

"M" activity was observed most clearly in cinematographs of an area of the auricle approximately 1 cm. square photographed under powerful illumination and with a special magnifying lens. Contracting muscle segments as small as 0.2 to 0.8 mm. in diameter could be identified in the films. These segments appeared to contract asynchronously at rates generally between 800 and 1,500 per minute. "M" activity is diagnostic of auricular fibrillation; nothing similar is seen in normal sinus rhythm or in any of the other auricular arrhythmias.

Since "M" activity is not visible to the naked eye, the gross appearance of auricular fibrillation is due to the presence of the macroscopic ("L") contraction and relaxation waves which occur simultaneously with and superimposed on the sea of microscopic ("M") contractions and dilatations. "L" waves arise at a relatively regular rate of approximately 400 to 600 per minute even when electrical shocks are sent into the auricle at a much more rapid rate. Unlike the waves of the other auricular arrhythmias, the "L" waves of fibrillation appear to be independent of the ectopic focus; they arise at various sites on the auricles and travel in variable directions, regardless of the site of stimulation from which the arrhythmia is produced. The distance covered by the "L" waves is variable; some are scarcely visible to the naked eye, while others involve almost the entire auricle. The distinction between "M" activity and the weakest "L" waves is arbitrary; this suggests that the macroscopic waves merely represent fusion of the microscopic contractions and dilatations.

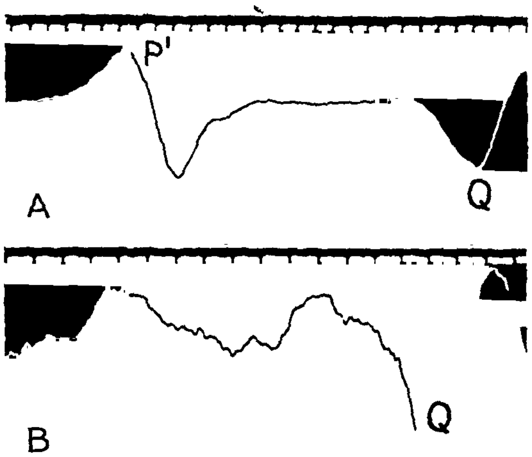

Fig. 3.—Esophageal lead cathode ray oscillograms from a single patient. *A*, during auricular flutter. The baseline is smooth at all times. *B*, after conversion to auricular fibrillation. Activity characteristic of the arrhythmia is now present. Time marker 1/120 second.

The presence of a circus movement as hypothesized by Lewis would be clearly manifested in high speed cinematographs of the fibrillating auricles. Minute circus movements occurring in microscopic areas of the auricles would be visible in the films recorded under high magnification which were used for exploration of the nature of "M" activity. Not only did the cinematographs fail to show any evidence of a circus movement, either macroscopic or microscopic, but several of the observations noted are entirely incompatible with the existence of such phenomena. (1) When both auricles were photographed simultaneously, they were seen to contract at the same time, or either one slightly before the other, or either one many times more frequently than the other. If a circus movement were present, one auricle would always contract before the other, and the number of over-all contractions of the two auricles would be the same. (2) The course pursued by the more vigorous "L" waves was clearly visible in the cinematographs. These waves often involved the entire width of the auricle from the auriculoventricular groove to the intercaval region. They did not turn around the venae cavae as hypothesized by Lewis, nor did they give rise to centrifugal daughter waves. (3) The observation that microscopic contractions and dilatations are present at all times in the fibrillating auricles is incompatible with the existence of an "excitable gap," which is an essential assumption of the circus movement theory. The conclusion is inevitable that no circus movement occurs in auricular fibrillation.

ELECTRICAL ACTIVITY IN THE FIBRILLATING AURICLE

Oscillographic studies of the fibrillating auricle in man and experimental animal confirm the observations made by means of the high speed cinematograph: Electrically as well as mechanically, auricular fibrillation is characterized by rapid, continuous, asynchronous activity of varying strength occurring at irregular rates. No evidence of a circus movement is seen in oscillograms of auricular fibrillation in either man or experimental animal.

Esophageal Lead Oscillogram of Clinical Auricular Fibrillation.—Esophageal lead oscillograms recorded from electrodes directly posterior to the fibrillating auricles in man differ from comparable tracings of the other auricular arrhythmias in several essential respects. No P′ wave is present.[15] The baseline throughout the tracings is irregular and jagged. The frequency, amplitude, and configuration of the deflections is extremely variable (fig. 3). Simultaneously recorded oscillograms from various auricular levels exhibit little or no synchronism. Two extreme orders of electrical activity, presumably the counterparts of the "M" and "L" activity observed in the cinematographs, may be distinguished in esophageal lead oscillograms of clinical auricular fibrillation. (1) Minute complexes of constantly changing configuration, generally 0.1 mv. or less in amplitude, are inscribed at frequencies up to several thousand per minute. (2) Large complexes, approximately 0.2 to 1.0 mv. in amplitude, occur at frequencies af about 350 to 600 per minute. These large complexes correspond to the familiar "f" waves of the fibrillation electrocardiogram.

Direct Lead Oscillogram of Experimentally Produced Auricular Fibrillation.—Except for differences directly attributable to the difference in location of the recording electrodes, the direct lead oscillogram of auricular fibrillation in the experimental animal is similar to the esophageal lead oscillogram of the clinical arrhythmia. No P′ wave is present; no isoelectric period is recorded (fig. 4); no synchronism between simultaneously recorded tracings is apparent. As in the esophageal lead oscillogram, both minute and large complexes are recorded from all regions of the auricles. Because of the greater proximity of the recording electrode, however, the deflections inscribed in the direct leads exhibit a wider range of sizes and frequencies than do those in the semidirect leads. (1) Minute complexes, an estimated 50 to 500 μv. in amplitude, occur at the astonishingly high frequency of approximately 7,000 to 20,000 per minute. Such deflections are too weak and too rapid to be recorded by standard electrocardiographic equipment. (2) Large complexes, corresponding to the "f" waves of the electrocardiogram, vary from 3 to 10 mv. in potential and are inscribed at rates from 500 to 1,000 per minute. An intermediate type of complex, varying from an estimated 0.5 to 3 mv. in potential, was frequently recorded from the appendix. The electrical activity represented by the intermediate complexes probably is responsible for the grass-like baseline and irregularities of the "f" waves seen in limb lead electrocardiograms of clinical auricular fibrillation.

---

[15] The presence of a P′ wave in auricular flutter has been demonstrated.

The chaotic nature of the electrical activity manifested in oscillograms of auricular fibrillation is incompatible with the existence of a circus movement. If a single excitation wave traveled around the fibrillating auricles along a roughly circular path, as hypothesized by Lewis, some type of synchronism would be present in simultaneously recorded leads from various sites on or near the circuit. Although direct auricular and esophageal lead oscillograms were recorded simultaneously from numerous combinations of electrode positions, in every instance the tracings were entirely or almost entirely asynchronous. Furthermore, the absence of isoelectric intervals in the oscillogram indicates that the "isoelectric gap," which is essential to the perpetuation of the circus movement, does not exist.

EFFECT OF DRUGS ON THE FIBRILLATING AURICLE

The fact has long been known that auricular fibrillation is produced when the auricular rate reaches a certain critical level, called the fibrillation threshold rate. High speed cinematographs and cathode ray oscillograms recorded while the auricles are electrically stimulated at gradually increasing rates reveal that certain manifestations of conduction failure appear before the fibrillation threshold is reached, grow progressively more pronounced, and finally culminate in the chaotic mechanical and electrical activity characteristic of auricular fibrillation. As the accelerating rate of discharge from the ectopic focus approaches the fibrillation threshold, the contraction waves seen in the cinematographs are conducted over the auricles at progressively slower rates so that each wave leaves the ectopic focus a shorter interval after the preceding wave has terminated, and the length of auricular diastole is consequently shortened. The electrical counterpart of this mechanical phenomenon is a progressive lengthening of the stimulus-to-intrinsic interval and a slight notching and splintering of the auricular deflection indicative of a slowing of the rate of conduction of the excitation wave. Such conduction slowing is attributable to incomplete conduction recovery during the shortened cardiac cycle and reduced period of auricular diastole. Thus, as a result of these two factors—slowing of conduction and shortening of diastole—the auricular musculature has increasingly less time in which to recover its ability to conduct succeeding excitation and contraction waves. Auricular fibrillation ensues when the rate of discharge from the ectopic focus reaches a level at which conduction is so impaired and diastole so short that the auricle is unable to recover from one contraction and excitation process rapidly enough to receive and conduct the succeeding wave in a coordinated fashion.

The above observations indicate that the fibrillation threshold of a given auricle is determined by the conductivity of the auricular musculature. This conclusion is supported by the observation that the rate of stimulation required to produce fibrillation is lowered after administration of quinidine or digitalis, both of which have been shown to depress auricular conductivity by delaying conduction recovery.[14] Conversely, a more rapid rate of stimulation is required to obtain fibrillation after than before administration of acetylcholine, a drug that has been shown to accelerate auricular conduction recovery and to improve auricular conductivity.

Since auricular fibrillation occurs when the rate of discharge from an ectopic focus on the auricles reaches the fibrillation threshold, and since the fibrillation threshold is determined by the conductivity of the auricular musculature, the effect of a given agent on the fibrillating auricle depends on its ability to alter the activity of the ectopic focus and/or auricular conductivity.[16] The action of the various antifibrillary drugs does not occur at an "excitable gap" on a hypothetical circus pathway. Rather, any agent that decreases the rate of discharge from the ectopic focus and/or facilitates auricular conductivity will tend to terminate auricular fibrillation. Any agent that increases the rate of discharge from the focus and/or depresses auricular conductivity will tend to precipitate or perpetuate auricular fibrillation. In the present study, the same methods of direct observation used to explore the mechanism of auricular fibrillation were further applied to determine the precise effects on the fibrillating auricle of the two commonest therapeutic agents, quinidine and digitalis.

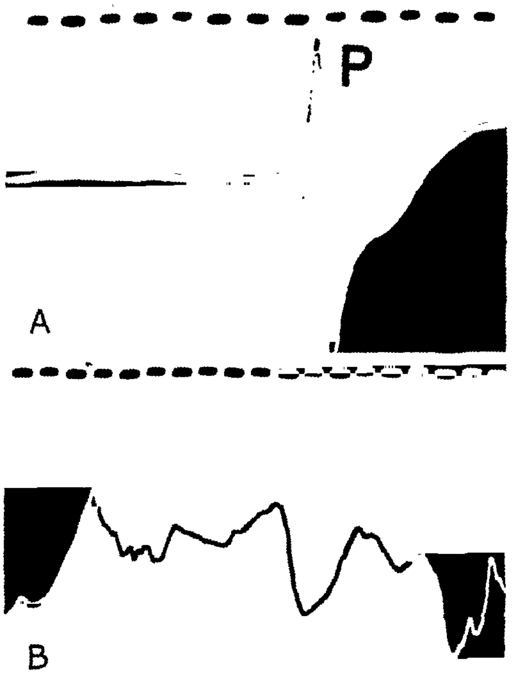

Fig. 4.—Direct auricular lead cathode ray oscillograms from a dog. *A*, regular sinus rhythm. Note the smooth baseline. *B*, after the production of auricular fibrillation, the activity has changed completely. Time marker 1/120 second.

Effect of Quinidine on the Fibrillating Auricle.—Both cinematographically and electrocardiographically, quinidine was found to depress conduction in an auricle beating at any specific controlled rate and thereby to lower the fibrillation threshold. When administered during auricular fibrillation, quinidine proved capable of slowing the rate of discharge from the ectopic focus and thereby terminating the arrhythmia.

---

[16] Since the ectopic focus of auricular fibrillation lies in cardiac muscle, the possibility exists that any agent that drastically depresses auricular conductivity would tend to prevent the conduction of impulses out of the ectopic focus and consequently would slow the rate of discharge from the focus.

As noted earlier, manifestations of conduction failure appear in the auricle before the onset of fibrillation and grow progressively more pronounced as the rate of discharge from the ectopic focus is increased. High speed cinematographs of aconitine-produced auricular fibrillation recorded during administration of quinidine exhibit the reverse of this process: The quinidine-induced slowing of the rate of discharge from the focus is accompanied by an improvement in auricular conduction which outweighs the direct conductivity-depressing action of the drug. After quinidine is administered, the "L" contraction and relaxation waves in the fibrillating auricle gradually become stronger and travel greater distances. The "M" activity progressively decreases in rate and exhibits increasing coordination. As the auricular rate drops below the fibrillation threshold, the "M" activity disappears and the waves are seen to initiate from a single site and travel across the entire contractile surface of the auricle. Further slowing of the rate of discharge from the ectopic focus is marked by an increase in the regularity and rate of conduction of the contraction waves.

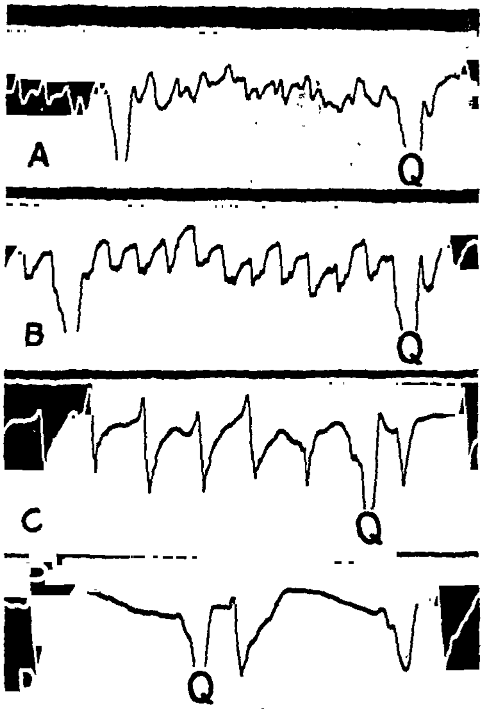

Fig. 5.—Direct auricular lead oscillogram from a dog exhibiting transitions from fibrillation to auricular tachycardia induced by quinidine (time markers 1/120 second). *A*, untreated fibrillation. *B*, fibrillation immediately following quinidine. The oscillations occur at a slightly slower rate than in *A* and bear some resemblance to one another. *C*, intermediate stage in the transition from fibrillation to flutter. Note the increased amplitude and decreased rate of the deflections. Aberration of the P' wave is pronounced. *D*, auricular tachycardia. The P'-Q interval is prolonged.

The electrical counterpart of these mechanical changes is observed in direct lead oscillograms from the fibrillating auricle of the dog recorded during quinidine administration. After administration of the initial dose, the large complexes in the oscillogram exhibit a gradual increase in amplitude and decrease in frequency, as well as somewhat greater regularity in rate and configuration. The minute complexes grow progressively smaller until, after additional quinidine is received, they disappear from the tracings, and the baseline between the large complexes becomes smooth. As the auricular rate drops below the fibrillation threshold and continues to decline, the chaotic pattern of fibrillation is often replaced by the regular and symmetrical auricular deflections of flutter, tachycardia, and finally by normal sinus rhythm. The large complexes in simultaneously recorded direct lead oscillograms exhibit increasing synchronism after the initial dose of quinidine is injected, culminating in the achievement of complete synchronism with the onset of flutter or a slower-rate rhythm (fig. 5). This sequence of events often occurs clinically after quinidine.[17] In our experiments, the sequence of events leading to the termination of auricular fibrillation by quinidine was often cinematographically and electrographically similar to that observed when the rate of discharge from an aconitine-produced focus is slowed by direct cooling. If the rate of discharge from the ectopic focus declines suddenly to below the rate from the sinus node, direct conversion to normal sinus rhythm is achieved. If the rate from the focus falls gradually, flutter and/or tachycardia may appear before normal rhythm is restored.

Effect of Digitalis on the Fibrillating Auricle.—Digitalis, like quinidine, depresses auricular conduction at rapid auricular rates and thereby lowers the fibrillation threshold. Unlike quinidine, which has an atropine-like effect, digitalis causes an increase in vagal tone, which largely determines its effect on the rate of discharge from the ectopic focus. In clinical and experimentally produced auricular arrhythmias, both digitalis and vagal stimulation usually decrease the rate of discharge from an ectopic focus which is discharging relatively slowly, as in paroxysmal auricular tachycardia. Both measures tend to increase the rate of discharge from the ectopic focus when the auricular rate is rapid, as in flutter and fibrillation. Digitalis, therefore, tends to convert flutter into fibrillation and to perpetuate fibrillation.

The effect of digitalis on the electrical activity in the fibrillating auricle was observed in direct lead oscillograms from experimental animals and in esophageal lead oscillograms from human subjects. In the experimental animal, tracings recorded during digitalization show a progressive decline in amplitude and increase in rate of the large auricular complexes, with a smoothing of the baseline between ventricular complexes. In man, as in dog, the amplitude of the large complexes was greatly reduced after digitalization, and the baseline between ventricular complexes was smoother than before treatment (fig. 6). The decrease in auricular electrical activity is seen in the electrocardiogram of patients with auricular fibrillation who have been freely digitalized.[18]

High speed cinematographs of the fibrillating auricle taken after digitalization reveal a distinct reduction in auricular size. In addition, the fibrillatory movements are greatly diminished, and the large contractions appear to be restricted.

[17] Sokolow, M.: Quinidine in the Treatment of Benign Auricular Fibrillation with Repeated Emboli, Am. Heart J. **18**: 497, 1939.

[18] Hart, T. S.: Quinidin in Auricular Fibrillation, Arch. Int. Med. **30**: 593 (Nov.) 1922.

Many questions concerning the effects of drugs on the fibrillating auricle remain unanswered. The precise pharmacologic action responsible for the ability of quinidine to decrease the rate of discharge from an ectopic focus has not yet been established. Why digitalis and vagal stimulation usually slow the activity of an ectopic focus during tachycardia but tend to increase the activity of the focus during flutter and fibrillation is unknown. These and many other unsolved problems concerning auricular fibrillation and the slower rate auricular arrhythmias are now under investigation. At present, this much may be stated: Direct observation in man and dog establishes that auricular fibrillation represents an advanced degree of conduction failure which occurs when the rate of discharge from the ectopic focus reaches a certain critical level. Since no circus movement is present in the fibrillating auricle, termination of the arrhythmia is not achieved by the interruption of an "excitable gap" on a circus pathway. Rather, fibrillation ceases when the degree of conduction failure is reduced sufficiently to permit orderly conduction of contraction and excitation waves from the ectopic focus to the extremities of the auricles. This concept, together with a knowledge of the pharmacology of currently available drugs, provides a more rational basis for the therapy of auricular fibrillation than any heretofore advanced.

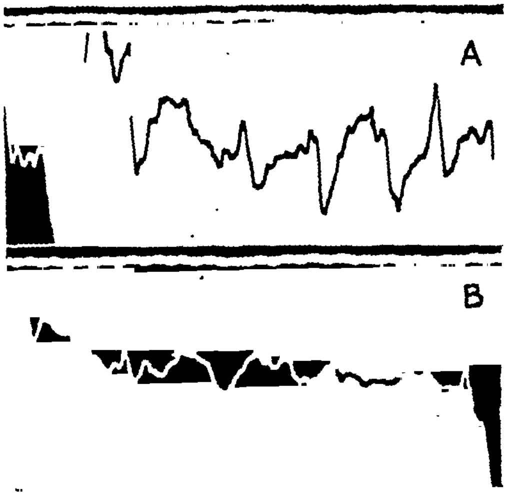

Fig. 6.—Direct auricular lead oscillogram from a dog showing auricular fibrillation. *A*, before digitalization. *B*, after digitalization. After digitalization, the oscillations are of decreased amplitude and appear to occur at a more rapid rate. (Time marker 1/120 second).

SUMMARY AND CONCLUSIONS

Direct and extensive observation of the fibrillating auricle in man and experimental animal establishes that previous theories concerning the mechanism of auricular fibrillation are invalid.

The mechanical and electrical activity in clinical auricular fibrillation is similar to that observed in the experimentally produced arrhythmia.

The motion of the fibrillating auricle was directly visualized in high speed color cinematographs of the exposed heart recorded in human subjects during surgical removal of auricular appendix and in experimental animals during bouts of fibrillation produced by local application of aconitine or electrical stimulation. In both man and experimental animal, the cinematographs revealed the presence of chaotic, continuous, rapid mechanical activity of a type never before described. Microscopic muscle bundles throughout the contractile portions of the auricular musculature undergo rapid and heterorhythmic contractions which cause a constant change in the silhouette and surface configuration of the fibrillating auricle. Superimposed on the microscopic contractions, relatively rhythmic contraction and relaxation waves arise at various sites on the auricle and travel for measurable distances in variable directions. No evidence of a circus movement, either macroscopic or microscopic, is visible in cinematographs of the fibrillating auricle of man or experimental animal.

Cathode ray oscillograms of auricular fibrillation recorded from direct auricular leads in experimental animals and from esophageal leads in man demonstrate the presence of chaotic, continuous, noncyclic electrical activity occurring in all portions of the auricles and corresponding to the microscopic and macroscopic mechanical events visualized in the cinematographs. Minute complexes of variable configuration are inscribed throughout the oscillograms at exceedingly rapid and highly irregular rates. The electrical events represented by such complexes are not recorded by standard electrocardiographic equipment. Larger complexes, also of variable configuration but lower in frequency and less irregular in rate than the minute complexes, are recorded from all areas of the auricles. Simultaneously recorded oscillograms from various combinations of sites on the fibrillating auricles exhibit little or no synchronism. The chaotic and continuous nature of the electrical activity in auricular fibrillation is incompatible with the existence of a circus movement.

Cinematographic and oscillographic study of the onset of auricular fibrillation indicates that the arrhythmia represents an advanced degree of conduction failure which occurs when the rate of discharge from the ectopic focus is too rapid to permit adequate conduction recovery in the auricle between successive contraction and excitation processes. Any agent that reduces the degree of conduction failure either by slowing the rate of discharge from the ectopic focus or by improving auricular conductivity tends to terminate auricular fibrillation. The therapeutic action of antifibrillary drugs is not due to an alteration of an excitable gap on a circus pathway.

Direct observation of the effects of quinidine and digitalis on the fibrillating auricle shows that both agents depress auricular conductivity at rapid auricular rates and thereby lower the fibrillation threshold. The antifibrillary action of quinidine is related to the ability of the drug to slow the rate of discharge from an ectopic focus on the auricles and consequently to mitigate the conduction failure induced by rapid auricular rate. Digitalis generally increases the rate of discharge from the rapidly discharging focus in the fibrillating auricle and consequently tends to perpetuate auricular fibrillation.

VENTRICULAR TACHYCARDIA

REPORT OF A CASE IN WHICH "PRONESTYL" WAS EFFECTIVELY USED AFTER FAILURE WITH QUINIDINE

C. Warren Irvin Jr., M.D., Columbia, S. C.
and
Frank B. Cutts, M.D., Providence, R. I.

Recently we have observed the occurrence of ventricular tachycardia in a young man, approximately three months after myocardial infarction. Esophageal leads were helpful in proving the diagnosis. Although the arrhythmia was refractory to large amounts of quinidine sulfate (by oral and intravenous administration), atropine, magnesium sulfate, and diethylaminoethanol, it finally responded, with the patient almost at the point of death, to oral administration of procaine amide hydrochloride ("pronestyl").

REPORT OF A CASE

J. A. B., a white man, 35, was admitted to the Rhode Island Hospital on March 3, 1950. His symptoms, physical findings, laboratory studies, and serial electrocardiograms indicated an acute anteroseptal myocardial infarction. No arrhythmias were noted during daily examinations and his course was benign. He was not given quinidine or digitalis, and was discharged on the 31st day, on limited but increasing activities.

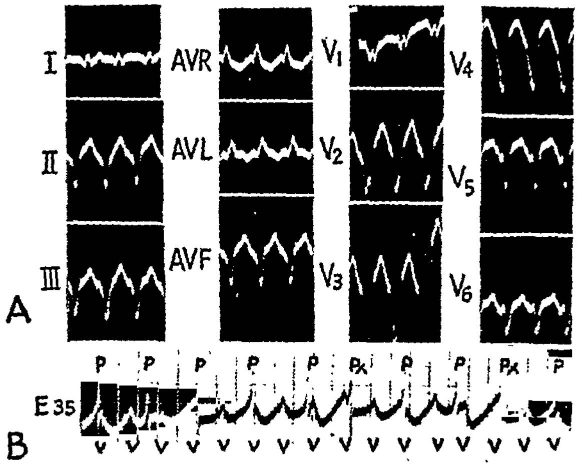

Fig. 1.—*A*, electrocardiogram made on admission. Ventricular tachycardia. Rate 190. *B*, esophageal lead at 35 cm. P indicates auricular complexes (rate 110); Px, auricular extrasystoles; V, ventricular complexes.

He remained entirely asymptomatic until 48 hr. before his second admission, on June 11, 1950 (53 days after discharge, and 86 days after the onset of infarction). At this time he had been awakened by vague left chest and shoulder pain and simultaneous palpitation. The attack subsided spontaneously after four hours, only to recur 24 hr. later. Despite narcotics, the tachycardia and pain persisted and he was rehospitalized.

Physical Examination.—The blood pressure was 104/80; pulse rate, 168; respirations, 24; rectal temperature, 101.6 F. He was sweating, slightly dyspneic, apprehensive, and acutely ill. Rales and crackles were heard at both lung bases, more marked on the right. The heart was not enlarged. The sounds were clear and perfectly regular. A loud to-and-fro friction rub appeared and lasted a few hours on the second day. The liver was not palpable and results of physical examination were otherwise not remarkable.

Laboratory Studies.—Results of laboratory studies showed a white blood cell count of 15,250 per cubic millimeter and a sedimentation rate of 38 mm. per hour. Chest x-rays showed moderate pneumonitis at the right base. An electrocardiogram made on admission, with esophageal leads made on the following morning, was diagnostic of ventricular tachycardia (fig. 1). The clinical impression was bronchopneumonia with ventricular tachycardia, and probably pericarditis. A small recurrent myocardial infarction could not be excluded.

Treatment and Course.—Bishydroxycoumarin (dicumarol®) and penicillin were given in adequate doses. Figure 2 summarizes the treatment with quinidine and procaine amide hydrochloride ("pronestyl") during the tachycardia. Severe diarrhea was noted on the first trial with quinidine, and on the second day vomiting and diarrhea were so severe (after 3.0 gm. in eight hours) that further quinidine sulfate by mouth was omitted. Atropine sulfate (1.6 mg. intravenously) given at the height of quinidine effect was of no avail. An electrocardiogram suggested moderate quinidine toxicity (fig. 3). On the third day magnesium sulfate (20 cc. of 25% solution) administered intravenously was of no value, and later, diethylaminoethanol (5.6 gm. intravenously administered in one hour) did not slow the rate significantly or alter the electrocardiogram. Because the patient showed gradual and progressive deterioration, intravenous quinidine (1.95 gm. quinidine lactate diluted to 200 cc. with 5% dextrose in water) was given on the fourth day. After approximately two-thirds of the solution had been given during a 40-min. period, severe vomiting and a short convulsive seizure occurred. The rate of administration was slowed for 10 min. and then stopped for 15 min. because of protracted vomiting. After resumption of use of the drug, tachypnea, profuse sweating, flushing, generalized weakness, and drowsiness became prominent. Although the ventricular rate was slowed moderately, the electrocardiograms (made every five minutes) were, in rate and contour, almost exactly like those seen after oral administration of quinidine. The toxic effects of the drug were felt to be too severe to permit further use.

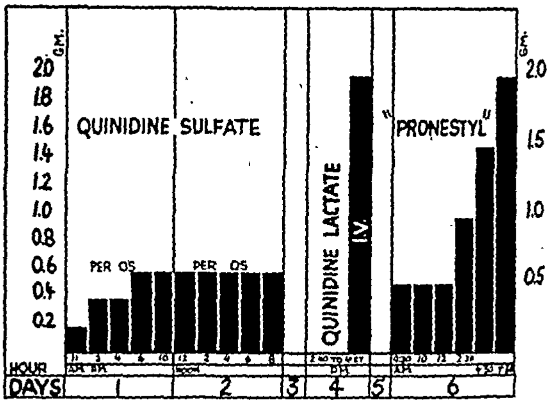

Fig. 2.—*A summary of the treatment with quinidine and procaine amide hydrochloride ("pronestyl") during hospital admission for tachycardia.*

On the sixth day the patient suddenly became worse, shock appeared, and he was not expected to live more than a few hours. "Pronestyl" (procaine amide hydrochloride) became available for the first time, and was given as shown in Figure 2. The patient remained in critical condition until, 12 hrs. after he was given the drug, the rhythm reverted. An electrocardiogram made shortly after the last dose showed severe quinidine-like effects (fig. 3). After reversion a dramatic improvement occurred, and the fol-

E. R. Squibb & Sons, New York, N. Y., supplied "pronestyl" for therapeutic trial.

lowing morning the blood pressure was 104/82 and the skin was warm and dry. An electrocardiogram showed normal sinus rhythm and, again, changes similar to those seen with quinidine (fig. 4).

Procaine amide hydrochloride, 500 mg., was continued every fourth hour, and gradual clinical improvement was observed. Forty-eight hours after reversion, runs of bigeminal rhythm were noted, and the drug was increased to 1 gm. every four hours. It is of interest that the ventricular extrasystoles were different in form from the QRS complexes during the tachycardia, and thus presumably arose from a different focus. The bigeminy (fig. 4) became more persistent, and the patient noted a generalized flushed sensation, and later mild nausea, following a single dose. The nausea disappeared quickly and the flushed sensation decreased in intensity when the drug was continued at the same dosage. The administration of procaine amide hydrochloride was maintained at 1 gm. every four hours for six days, and the rhythm became slow and regular. Then the dosage was reduced gradually, and terminated 10 days later. When the dosage was reduced to 250 mg. every four hours, a moderate number of ventricular extrasystoles (as many as to 14 a minute) reappeared. These caused no symptoms, and the tachycardia did not recur. The patient was discharged, feeling well, on the 31st hospital day.

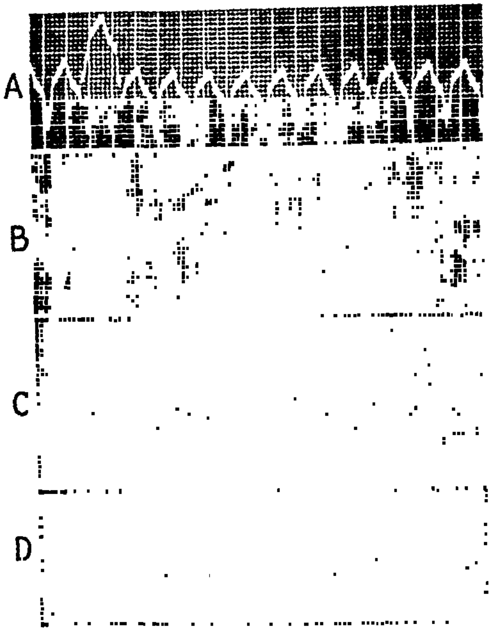

Fig. 3.—All tracings in Lead II. *A*, before treatment. Rate 190. *B*, after 3.0 gm. of quinidine sulfate by oral administration over a period of eight hours. Rate 133. Some widening of QRS complexes. *C*, thirty-six hours after intravenous quinidine. Rate 178. QRS complexes similar to those in *A*. *D*, just after 6 gm. of procaine amide hydrochloride ("pronestyl") given in 10-hr. period by mouth. Rate 112. QRS complexes considerably widened.

COMMENT

"Pronestyl"—procaine amide hydrochloride—(p-amino-N-[2-diethylaminoethyl] benzamide hydrochloride), a derivative of procaine, has been studied intensively by Mark and others,[1] and has been found to be particularly useful for the treatment of ventricular tachycardia. It may be successful when quinidine has failed, and has minimal toxic effects in therapeutic doses. The drug may be given by mouth or intravenously (100 mg. per cubic centimeter). As in this case, quinidine-like effects may be noted in the electrocardiogram following its use. Procaine amide hydrochloride appears to be a useful drug in treating ventricular tachycardia.

SUMMARY

A proved case of ventricular tachycardia refractory to quinidine was reverted with "pronestyl" (procaine amide hydrochloride). Procaine amide hydrochloride has an action similar to quinidine on ventricular muscle, but apparently does not exhibit the toxic effects of the latter drug. The drug appears to be effective in ventricular tachycardia and deserves further trial.

ADDENDUM

This patient's course, since this report was submitted, is of interest. One week after discharge, he was readmitted with a second bout of ventricular tachycardia (electrocardiogram tracing as in Fig. 1). This was again controlled by oral administration of procaine amide hydrochloride ("pronestyl") although he vomited considerably when it was administered. He was discharged on July 28, 1950, and instructed to take 1 gm. of the drug on arising and at bedtime, and 0.5 gm. every three hours during the day. He was examined on three occasions thereafter in the outpatient clinic. He reported one short bout of tachycardia, readily controlled by an extra dose of procaine amide hydrochloride, but complained of occasional nausea after taking the drug and could not take larger amounts routinely. Occasional-to-numerous extrasystoles were noted at each visit.

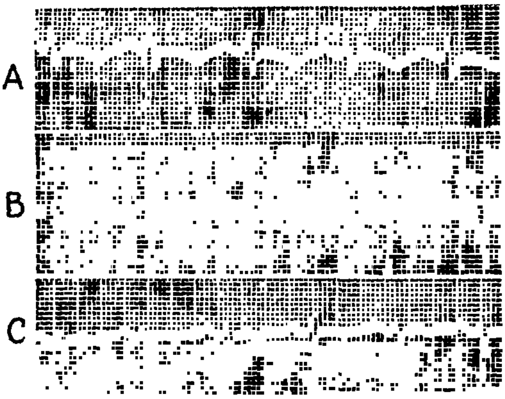

Fig. 4.—All tracings in Lead II. *A*, shortly after tracing shown in Figure 2*D*. Normal sinus rhythm. Rate 75. *B*, ventricular extrasystoles while procaine amide hydrochloride ("pronestyl"), 1 gm. every four hours, was being given. These were more clearly shown to be ventricular extrasystoles in other leads and differed from the complexes seen during the tachycardia. *C*, two days after all medication was stopped.

On Sept. 12, 1950, he died suddenly after a bout of palpitation, which his family said was similar to his previous attacks. Autopsy, limited to the heart, revealed an old thrombosis in the anterior descending branch of the left coronary artery, and a large healed infarct involving the anterior left ventricle and the anterior two-thirds of the interventricular septum. In this case it seems apparent that ventricular irritability was persistent over a three-month period. Although procaine amide hydrochloride was successful in terminating at least two attacks of ventricular tachycardia, it did not prevent, in tolerated dosage, ventricular extrasystoles or what was apparently a fatal arrhythmia.

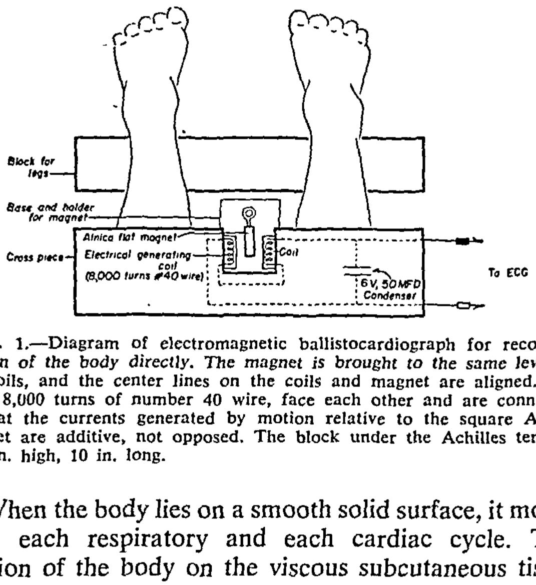
BALLISTOCARDIOGRAPHY IN MEDICAL PRACTICE

William Dock, M.D., Harry Mandelbaum, M.D.
and
Robert A. Mandelbaum, M.D., Brooklyn

Seventy years elapsed between the description by Gordon[1] of a method for graphically recording the motion of the body with each heart beat and Starr's Harvey Lecture[2] reporting how such curves could be used in routine clinical diagnosis. Most ballistocardiographs are bulky; the latest model to be described weighs over a ton without the recording mechanism.[3] However, since 1949 there have been available three systems for recording the body's motion with very simple attachments to any type of electrocardiograph,[4] and routine use by practitioners, industrial medical and insurance examiners has become a reality. Physicians not only use the ballistocardiograph on patients, but have it used on themselves as they enter the "coronary age." It therefore is desirable to put before them a brief description of this simple diagnostic method.



Block for legs
Base and holder for magnet
Alnico flat magnet
Cross piece
Electrical generating coil (8,000 turns #40 wire)
Coil
6V, 50MFD Condenser
To ECG

Fig. 1.—Diagram of electromagnetic ballistocardiograph for recording motion of the body directly. The magnet is brought to the same level as the coils, and the center lines on the coils and magnet are aligned. The coils, 8,000 turns of number 40 wire, face each other and are connected so that the currents generated by motion relative to the square Alnico magnet are additive, not opposed. The block under the Achilles tendons is 3 in. high, 10 in. long.

When the body lies on a smooth solid surface, it moves with each respiratory and each cardiac cycle. This motion of the body on the viscous subcutaneous tissue can be recorded by the change in width of a shadow cast by the body on a photocell, by pressure of the body against any device for recording pulses, or by motion of a coil attached to the body and placed in the field of a magnet fixed to the earth.[4] Likewise, the pull of the body transmitted through the subcutaneous tissues to the table on which it lies can be recorded in many different ways. Both high frequency and critically damped, low frequency, table type ballistocardiographs are too bulky for routine use. After much experience with other methods, we have chosen a two coil electromagnetic pick-up, which lies across the shins, as the most dependable, the lightest, and least bulky. It contains no elements, such as batteries, that require replacement. Curves taken with this instrument on subjects lying on the Starr table are almost identical with those inscribed by the table. Since the flat fixed magnet is placed between the coils, the variation due to slight change in magnet-coil distance inherent in our previous single coil models has been eliminated. The instrument has one great defect—it is so simple and cheap that no manufacturer has found it worthwhile to make. A diagram (fig. 1) has been useful to several dozen physicians who have made their own ballistocardiographs.

INTERPRETATION OF THE CURVES

Our understanding of the significance of the deflections is due to the experiments of Hamilton[5] and Starr.[6] When the viscera or rib cage moves with respiration, the body moves in the opposite direction (Newton's third law: to every action, there is an equal and oppposite reaction). Since the rib cage moves headward and the viscera footward, the ballistopneumogram depends on the type of respiration. Our ballistocardiograph is designed to filter out the respiratory component except for a very slight change in baseline. Unfiltered photoelectric pick-ups or the low frequency tables show respiratory waves far larger than those of the cardiac cycle; these are absent in unfiltered electromagnetic recording or with high frequency tables.[3]

The ballistocardiographic waves result from recoil from ventricular ejection, which pushes the body footward, and impact or deceleration of blood moving in the great vessels, which moves the body in the same direction as the blood. Both types of force may operate at one time, and the ballistocardiograph records the motion due to the balance of all these forces. In any case, the force equals mass times square of velocity of the blood. If stroke volume is constant, but mean velocity doubled when the duration of systole is halved, the ballistic forces will be increased fourfold; if systole is prolonged by 29%, the ballistic forces will be halved. The size of the ballistic waves, therefore, will vary with stroke volume only when diastolic pressure, aortic elasticity, and myocardial vigor are constant, and the size of the waves cannot be used as an index of stroke volume in the presence of heart disease, very high or low diastolic pressures, or disease of the aorta.[6] A young man with aortic insufficiency shook the bed at each heart beat, and his I-J wave was 10 times the normal amplitude and could be inscribed only with a fivefold decrease in sensitivity of the

galvanometer, yet it is unlikely that the total output of both ventricles was more than twice normal. In shock, I-J is relatively large in relation to stroke volume, because diastolic pressure is low.

The normal curve (fig. 2A) has three main systolic waves: I, a footward wave when ejection begins; J, a headward wave when impact on the arch of the aorta predominates, and K, a footward wave due to deceleration as the main mass of blood moves down the aorta. L and N, headward waves sometimes fused into a single wave, occur in early diastole. H, a headward wave, usually occurs during isometric contraction at the onset of systole, but with long P-R intervals or presystolic gallop, it may begin before the Q wave of the electrocardiogram, and at fast rates, N and H may be fused into a single presystolic wave ending in early systole.

During respiration, there may be as much as 40% decrease from the maximal amplitude in the I-J waves of normal subjects, and reciprocal changes in the height of I and J also occur. Decrease in vigor of ventricular contraction, with constant stroke volume and diastolic pressure, leads to decrease in I-J, notching of J, and increased depth of K.[6] In coarctation of the aorta without heart failure, in shock, and in some adults with systolic pressures below 110 mm. Hg., K is absent or distinctly reduced. While L may rarely be as high as J in normal subjects, it often is prolonged and tall in mitral stenosis and in cases of gallop rhythm.

There are no ballistocardiographic curves pathognomonic of specific diagnostic entities, but in North America there is a very high correlation between angina pectoris, myocardial infarction, or scars due to infarction, and curves with pronounced respiratory variation, or complete obliteration of the normal pattern. Such curves also are seen in congestive failure with low cardiac output, but here severe myocardial weakness is already known to be present.

In heart failure, the ballistocardiograph is most useful when it reveals normal or high amplitude waves, always suggestive of aortic insufficiency or high cardiac output and sometimes leading to the discovery of an unsuspected beriberi, toxic diffuse goiter, osteitis deformans, arteriovenous fistula, or cirrhosis of the liver. Anemia with heart failure may be associated with waves that are normal and of great size, but that revert to low, bizarre complexes as hemoglobin levels return to normal. Acute myocarditis is frequently accompanied by decided ballistocardiographic abnormality as the only objective evidence of cardiac involvement. This is less striking when fever is high and blood flow very great. It should be noted that in scarred hearts, the L-M complex in diastole may simulate the normal J-K, which in turn may be so diminished that on inspection of the curve the examiner mistakes systole for diastole. Simultaneous pulse or electrocardiographic traces are thus essential in these cases for correct interpretation of the ballistocardiographic records (fig. 2B).

It is our practice to record the ballistocardiogram after the routine electrocardiograms, with the patient under basal conditions and breathing normally. Further records are made with the breath held in deep inspiration and in deep expiration, and in suspected cardiac cases in which this gives normal records, the sequence is repeated after exercise such as the two step test. It has also been shown[7] that the ballistocardiogram taken after meals is abnormal in some cardiac patients with normal basal ballistocardiograms.

The records are interpreted in the light of what we already know of the patient. Thus deep K waves and pronounced respiratory variation in I-J are normal in the latter half of pregnancy, but may indicate that a hypertensive is on the verge of congestive failure. K waves as short as I, or absent K waves, might mean early shock in a person with bleeding ulcer, fast pulse, and normal pressure, might be normal for a man with familial hypotension, and would corroborate the diagnosis of coarctation in a hypertensive patient with weak or absent femoral pulsations. Notched ribs in the chest roentgenogram would prove that the coarctation was at the usual site. Deep K waves might be due to hypertension, to a rigid aorta, or, when associated with abnormal I-J waves, to heart failure, or severe scarring of the heart. In elderly subjects, varying combinations of all four factors may account for bizarre I-J and deep K waves. Bizarre waves and great respiratory variations are seen in pericardial tamponade.

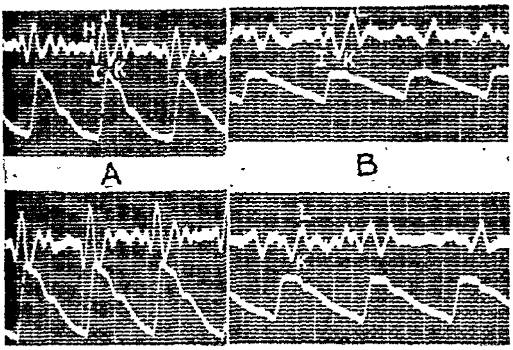

Fig. 2.—In all records, the upper trace is the ballistocardiogram, the lower trace is the radial pulse. *A*, the record from a normal adult at rest (upper pair of tracings) and after exercise (lower pair of tracings). *B*, record from a case of angina. The large L might be mistaken for J, and the extreme abnormality might escape detection, if the waves were not timed by comparison with the pulse. The waves are smaller in the lower record after exercise.

The ballistocardiographic record is read much as one reads the facies of a patient; it is not subjected to quantitative analysis, but is intuitively compared with the normal range for young adults and the variations noted by the observer or reported by others in groups of patients with specific diagnoses. Thus in a patient known to have angina or a previous episode of coronary disease, a normal ballistocardiogram on effort as well as rest is welcome evidence of excellent recovery of myocardial function, but does not rule out subsequent coronary episodes. Gradual return toward normal may continue for months after an infarct, but persistence of chaotic waves would make one suspect myocardial aneurysm, future congestive failure, and a relatively great risk of sudden death. Discovered in a patient with angina or in a person free of all other signs of heart trouble, such a tracing would lead one to give the same advice as in a case of myocardial aneurysm accidentally detected by routine chest roentgenograms. Less pronounced abnormalities would have a significance comparable with that of a deep Q and spiked inverted T, while minor abnormalities would be accepted as evidence of previous injury with minimal residual defect.

---

[7] Berman, B.; Braunstein, J. R., and McGuire, J.: The Effect of Meals on the Electrocardiogram and the Ballistocardiogram in Patients with Angina Pectoris, Circulation 1: 1017 (April) 1950.

It must be borne in mind, however, that while small but strategically placed scars can cause such maximal change in the electrocardiogram as bundle branch block, changes in the ballistic pattern not associated with hypertension or a rigid aorta represent results of defects in *expulsive force of the ventricle* and must be due to lesions of appreciable extent. They do not lead to an etiologic diagnosis, for the scarring due to healed beriberi cannot be distinguished by its functional effects from that due to coronary disease, heart failure, or acute myocarditis. No one should be confined to bed or even to his home because of abnormal ballistocardiograms alone. Men have lived active lives for decades with grade 4 murmurs, complete heart block, auricular fibrillation, or bundle branch block, and they undoubtedly will do so with grade 4 ballistocardiograms. Yet insurance companies would profit by refusal to insure such cases routinely. Starr's experience suggests that the prognosis is worse for a man in apparent good health with grade 4 curves than for a similar patient with bundle branch block.[2]

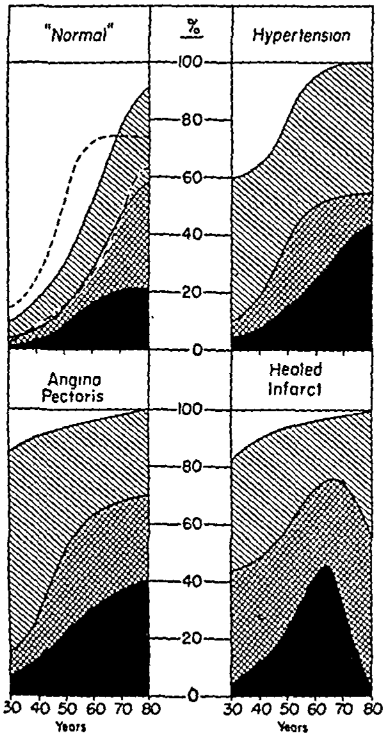

Fig. 3.—Diagrams illustrating the percentage distribution of normal and abnormal ballistocardiograms in control subjects and in groups of diseased patients of various ages. White areas represent normal traces at rest and after exercise; cross-hatched areas, definite abnormality as defined in text; double hatched area, marked abnormality; black area, maximal abnormality. The dashes show incidence of grade 3 coronary sclerosis at autopsy in men[9a]; dots and dashes, same for women.[9b]

The records may be classified according to the four grades of Brown, Hoffman, and de Lalla,[8] based on the tracing obtained during normal respiration or, as in the accompanying figures, the over-all findings can be grouped as definite, marked, or maximal deviations from normal, based on the responses to exercise and held respiration, as well as on the resting ballistocardiogram with normal breathing. "Maximal abnormality" includes the cases with totally abnormal complexes of low amplitude under basal conditions (Brown grade 4). "Marked abnormality" includes those which, at rest or after exercise, showed notched J waves or low amplitude irregular I-J waves, usually becoming unidentifiable in expiration (Brown grade 3). "Definite abnormality" includes those which, at rest or after exercise, show unusual respiratory variation, with good amplitude during inspiration (Brown grades 1 and 2). As with changes in apical chest shadows and ventricular complexes of the electrocardiogram, the normal proceeds into maximal evidence of disease by imperceptible steps, so that any group of examiners or even the same examiner on different days will not classify 100 tracings or films in exactly the same way. Classification is useful for statistical study and for individual examination of all tracings for individual cases.

RANGE OF VARIATION IN BALLISTOCARDIOGRAMS IN HEALTH AND DISEASE

Using the above criteria, we have constructed four diagrams (fig. 3) to show the effects of age on the type of tracings encountered in health, in uncomplicated hypertension, in angina pectoris, and after myocardial infarction. Starr's[2] statistics suggest that normals with abnormal tracings will manifest heart disease within the decade far more frequently than those with normal tracings. Dry and his co-workers[9] have shown an incidence of coronary sclerosis in our population that explains in part why increasingly frequent abnormalities in electrocardiograms and ballistocardiograms are to be expected in "normal" persons over the age of 50. The ballistocardiogram, which is slightly altered by aortic rigidity, by emphysema, or even by *flabby abdominal walls*, as well as myocardial scars, naturally has the higher frequency of abnormalities.

The normal group (fig. 3) consisted of 100 consecutive subjects in whom there was no reason to suspect heart disease after evaluation of history and complete clinical examination. Sixty-two per cent of these patients were over 50 years of age. Our statistics demonstrate that one should expect normal or only slightly abnormal ballistocardiograms in well over 90% of patients who are under 50 years of age and who are without evidence of heart disease. Of our 48 "normal" subjects in the sixth decade, 22% had ballistocardiograms that were decidedly abnormal; the ballistic abnormalities were often accentuated by the two step exercise test.

The group of 78 hypertensive patients (fig. 3) had been evaluated by electrocardiogram, ballistocardiogram, and funduscopy. None of these patients was in congestive heart failure, and none had any complaints suggestive of coronary insufficiency. The abnormalities found in the ballistocardiograms increased in direct proportion to the severity of the hypertensive cardiovascular disease. The change in cardiac ejection evident in advanced hypertension is probably the result of a damaged myocardium working against an increased peripheral resistance.

None of the 152 consecutive cases of classical angina pectoris (fig. 3) gave a clinical history of myocardial infarction, but 16% of the patients had electrocardiographic changes indicative of serious heart disease, and such electrocardiographic findings were always associated with definite ballistocardiographic abnormality. Since only 12 patients (8%) of this series had normal resting ballistocardiograms, and of these, only two remained normal after the performance of exercise, the diagnostically important association of ballistocardiographic abnormality with angina pectoris is evident. Twenty-eight per cent of this group had maximal ballistocardiographic abnormalities; in an additional 21%, grade 3 or 4 ballistocardiograms developed after effort. In only 8% of this group of 152 patients with angina pectoris did exercise result in an improvement of the ballistocardiogram to a relatively normal state. We noted a general correlation between the severity of the angina and the abnormality of the ballistocardiogram. In three of the patients, myocardial infarctions developed after these studies were made. The ballistocardiographic abnormalities in these particular cases were grade 3 or 4.

[9] (*a*) White, N. K.; Edwards, J. E., and Dry, T. J.: The Relationship of the Degree of Coronary Atherosclerosis with Age in Man, Circulation 1: 645 (April) 1950. (*b*) Ackerman, R. F.; Dry, T. J., and Edwards, J. E.: Relationship of Various Factors to the Degree of Coronary Atherosclerosis in Women, Circulation 1: 1345 (June) 1950.

Ninety-eight patients who had survived one or more attacks of myocardial infarction form the basis for another portion of figure 3. Seven per cent of the patients had normal resting ballistocardiograms; about half of these became abnormal after effort. Of this series, 40% had maximal abnormalities in the ballistocardiogram; an additional 18% showed grade 3 or grade 4 changes after the performance of exercise. None of the patients was in congestive heart failure when these studies were made. Most of the ballistocardiograms were taken at least a year after the occurrence of the myocardial infarction. Of the men under 60, a great proportion were working. A definite correlation was found between the severity of the angina more recently noted by the patient and the abnormality of the ballistocardiogram. All the patients incapacitated by angina had grade 3 or 4 ballistocardiograms. At least eight of the patients with no complaints of angina but with distinctly abnormal ballistocardiograms had their activity limited because of episodes of congestive heart failure; 12% of the patients in this series were fully digitalized. Since these studies were completed, three patients have died from another episode of proved coronary thrombosis. Two of these had ballistocardiographic abnormalities classified as grade 3; the other was described as grade 4. A comparison of the incidence of maximal abnormality in older patients with angina and with healed infarction also suggests that survival is short in the latter group.

Thirty-seven men and seventeen women were studied by electrocardiograph and ballistocardiograph because of complaints of epigastric or chest pain. Careful study revealed extracardiac causes and no evidence of heart disease. Usually it was because of the excellent ballistocardiographic records in these patients, all of whose electrocardiograms were normal, that we were led to search for a noncardiac explanation of the chest pain. All but six basal ballistocardiograms were normal; these six were grade 1. Four of these six subjects were in the seventh decade of life. After performance of the two step exercise test in four other subjects, the normal basal ballistocardiograms became grade 1. Of this group of 54 patients, 5% were in the seventh decade of life; 21% were in the sixth decade; 39% in the fifth decade; 28% in the fourth decade, and 7% were less than 30 years of age. Cholecystitis was the final diagnosis in 12%; radiculitis or scoliosis in 33%; hiatus hernia in 9%; gastric or duodenal ulcer in 19%, and neurocirculatory asthenia in 19%. It will be necessary to follow these cases, especially those with definite ballistocardiographic changes, to see how many also had latent coronary disease.

Four patients with normal ballistocardiograms had chest pain associated with smoking, and no other cause was found for pain. We do not regard these as proved cases of coronary disease. On the other hand, we have seen two men in their twenties whose ballistocardiograms and finger pulses were definitely reduced by smoking one cigarette; these subjects had no chest pain or hypertension and had only moderate tachycardia while smoking. While sensitivity to vascular effects of smoking may thus be detected by the ballistocardiograph, it is apparent that not all those who get precordial discomfort from smoking will show changes in ballistocardiograms taken while smoking.

The following case histories illustrate the practical value of these studies in the evaluation of cardiovascular functions of various types of patients.

REPORT OF CASES

Case 1 (Chest Pain Not Due to Cardiovascular Disease).—Mrs. A. S., 55, suffered from pain in the left chest and the left shoulder. The pain began as she commenced her morning chores. It was aggravated by all physical effort; it was not related to food. Relief followed when she lay down; sleep was undisturbed. The blood pressure was 165/100 mm. Hg. Heart and lungs were normal. The history was suggestive of angina pectoris, but normal electrocardiograms and ballistocardiograms (fig. 2A) led us to seek another cause. Roentgenograms showed scoliosis of the cervical and thoracic spine, and orthopedic care resulted in complete relief of symptoms.

Case 2 (Hypertension Without Cardiovascular Symptoms).—Mr. A. I., 38, suffered from headaches but had no symptoms suggestive of cardiovascular insufficiency. His blood pressure was 195/110 mm. Hg. The eye grounds showed no hemorrhages or exudates. The heart was of normal size on roentgen study, but the configuration suggested left ventricular hypertrophy. The electrocardiogram was normal; the ballistocardiogram (fig. 4A) showed normal waves under basal conditions. After performance of the two step exercise test, the shortening of the I-J in comparison to the J-K and an increased respiratory variation followed. This ballistocardiogram was graded 2.[10]

Case 3 (Angina Pectoris).—Mr. I. M., 48, had been treated for peptic ulcer for 10 years and for 10 months had had precordial pain on walking. His blood pressure, renal function, and electrocardiograms, even after two step exercise, were normal. Glucose tolerance curves were normal; the blood cholesterol was only 224 mg. per 100 cc. The heart was normal on roentgen study. Ballistocardiograms were grade 1 under basal conditions, with smaller excursions and grade 2 respiratory variation after the two step test.

Case 4 (Healed Myocardial Infarction).—Mr. H. S., 63, had been kept in bed for nine weeks in 1947 because of myocardial infarction. He was not diabetic or hypertensive. His activity is now limited by angina of effort. The heart shadow was not remarkable, but the electrocardiograms showed a constant change compatible with healed anterior wall infarction. The ballistocardiogram (fig. 4B) was grade 3 under basal conditions, grade 4 after exercise, which evoked no pain or change in the electrocardiogram. The ballistocardiogram looked almost normal during abdominal compression with the breath held in expiration. On the basis of these findings and Brown's report on the value of abdominal binders for such patients,[11] such a support was prescribed. There has been a striking, but not complete, relief of symptoms.

---

[10] Makinson, D. H.: Changes in the Ballistocardiogram After Exercise in Normal and Abnormal Subjects, Circulation 2: 186 (Aug.) 1950.

CASE 5 (Acute Rheumatic Carditis).—Mr. M. L., 34, was seen in March, 1950, because of fatigability, weakness, aching "muscles," and loss of appetite. This illness had begun four weeks previously, with four days of fever, muscle pain, and arthralgia involving the knees, ankles, and wrists. The patient had then been given daily injections of penicillin, and after 10 days at home he returned to work. There was no past history suggestive of rheumatic fever. On examination, the patient did not appear ill; his temperature was normal; pulse was 96 per minute and regular, and the blood pressure was 130/80 mm. Hg. The apical heart beat was at the fifth intercostal space in the midclavicular line. The rhythm was regular, and the heart sounds were of good quality. A soft apical systolic murmur was noted. The lungs were clear. Examination of the abdomen revealed no palpable masses or organs. There was no articular swelling or tenderness. The laboratory studies showed hemoglobin 14.1 gm.; white blood cells, 9,750, with a slight polynucleosis. Urinalysis was normal. The sedimentation rate (Westergren) was 85 mm. in one hour. The electrocardiogram was normal on March 8, 1950. Figure 5A represents ballistocardiograms taken under basal conditions, the upper tracing having been taken on March 8, and the lower tracing on March 15. They showed tall L and H waves and a slurred J-K of low amplitude. He was kept in bed for several weeks until his sedimentation rate returned to normal. Electrocardiograms showed prolongation of the P-R interval during the second week, which persisted until the sixth week. The electrocardiogram taken at the eighth week was normal, and the ballistocardiogram (fig. 5B) was normal under basal conditions and after performance of the two step exercise test.

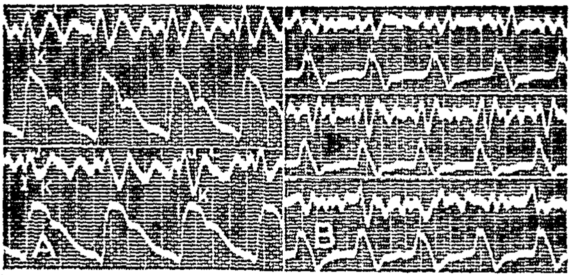

Fig. 4.—*A*, record from a hypertensive patient, 38, without cardiac symptoms (case 2). The upper record taken at rest is within normal limits, but the lower one registered after exercise shows pronounced respiratory variation and short J waves. *B*, record from a man, 63, two years after a myocardial infarction (case 4). Upper record taken in basal state is classified grade 3; middle taken with breath held in expiration shows better complexes; lower record taken after exercise is grade 4.

SUMMARY

A simple method of recording the ballistocardiogram is described, together with some case histories illustrating the value of the records in the study of various types of heart disease. The interpretation of the curves is discussed, and the incidence of various degrees of abnormality in different age groups and with certain common forms of cardiovascular disease is presented. The ballistocardiograph adds to our understanding of the vascular state of patients and is a sensitive indicator of vascular aging. If the heart muscle is sound, the tracings may be normal after myocardial infarction or in the presence of angina; if diastolic pressure is low or stroke volume large, the tracings may be normal in the presence of myocardial failure. Yet a patient with angina or with a silent healed infarct frequently has an abnormal ballistocardiogram as the only objective evidence of heart disease.

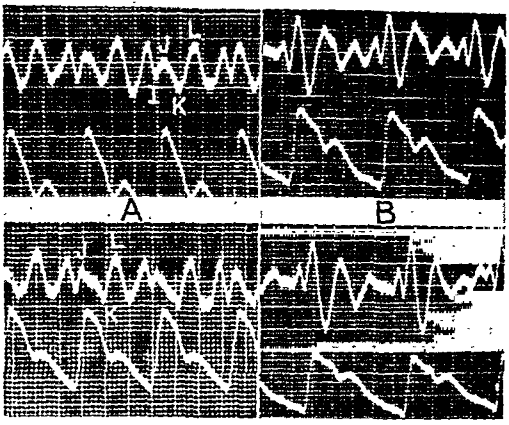

Fig. 5.—*A*, record from a man, 34, with rheumatic arthritis (case 5). At time of upper tracing, P-R interval was 0.16 sec. One week later, at time of lower tracing, it was 0.22 sec. The low J, tall L, and tall presystolic H are frequently seen in heart failure with gallop rhythm, but this man had only a soft systolic murmur. *B*, normal tracings on same man two months later with no clinical evidence of rheumatic activity Upper record was taken in basal state, lower one after exercise.

PROLAPSE OF THE URETHRA IN YOUNG GIRLS

J. Denny Moffett, M.D.
and
Rafe Banks Jr., M.D., Atlanta

Prolapse of the urethra in young girls has not been found very frequently in the past, and information on the diagnosis and management of this condition appears to be somewhat varied.[1] During the past six months four such patients have come under our care at Grady Memorial Hospital. Their condition previously had been undiagnosed and incorrectly treated. From these patients we have learned certain facts about the diagnosis and management of prolapse of the urethra which we feel to be of practical value. We present these cases to emphasize the occurrence of this condition in young girls and to offer a simple and effective form of treatment.

In 1937 Epsteen and Strauss [2] analyzed the literature and stated that the condition had been reported in 111 young girls. Keefe [3] has stated that 60% of cases occur in girls under the age of puberty.

From the Department of Urology, Grady Memorial Hospital, and Emory University School of Medicine.

ETIOLOGY

Many different theories have been offered to explain the etiology of this condition, but none are conclusive. It has been attributed to redundancy of the mucosa, to a neuromuscular dysfunction, to laxness of the tissues supporting the mucosa, and, finally, to stresses incident to coughing and straining. We have found no etiological factor in our cases.

CLINICAL FINDINGS

The principal clinical findings have been urethral bleeding, varying degrees of dysuria, and a mass presenting at the urethral meatus. The bleeding was noted as a "spotting" on the child's underclothes, and this directed the mother's attention to the mass. Pain on urination has varied from none to severe. The mass presenting at the urethral meatus may have an inflamed and edematous appearance, or, if the prolapse has been of sufficient duration, it may be ecchymotic.

Catheterized urine specimens, cystoscopy findings, and intravenous urograms were normal. The prolapse of the urethral mucosa involved the entire circumference of the lumen of the urethra in all cases. In no case was there any vaginal discharge.

DIAGNOSIS

The diagnosis of this condition offers no particular problem if one remembers that the prolapse involves the entire circumference of the meatus. When a mass is found anterior to the vaginal orifice, the correct relationship of the urethral canal to the mass must be ascertained. In a true prolapse the lumen is always directly in the center. Occasionally this condition must be differentiated from urethral polyp, caruncle, condyloma, urethrocele, and carcinoma. In urethral polyps the polyp is in the center of the lumen, and the mucosa is around it. In caruncle the lesion is usually found only on the posterior lip of the meatus and is very sensitive to touch. Condyloma has a warty, fungoid appearance and is usually multiple. Urethrocele is a herniation through the urethrovaginal septum and not through the urethral meatus itself. Carcinoma may be difficult to differentiate, and biopsy is occasionally necessary for diagnosis. The average age for carcinoma of the urethra is 53. It is extremely rare in young girls.

TREATMENT

There have been many operations devised and used to alleviate this condition. Some authorities have advocated only simple digital replacement. Gangrenous mucosal tissue precludes this procedure. Inserting a catheter into the bladder and then tying a ligature around it and the prolapsed mucosa, so as to allow the mucosa to slough off, has been done in the past. Livermore [4] has had success with his four-point fulguration, as has Hepburn [5] with his suprapubic approach. Sharp amputation of the prolapsed cuff, suturing together the severed end, and amputation with a cautery loop without suturing have been used with apparent success by various advocates.

Our routine of treatment has consisted of preoperative hot sitz baths until a line of demarcation has been established between normal urethral mucosa and the inflamed prolapsed mucosa. This is followed by a complete circular excision of the prolapsed mucosal cuff with the cautery loop along this line of demarcation, so that the entire prolapsed portion is removed. This excised portion is a 360 degree cuff of tissue with a definite lumen. We do not feel that approximating the cut edges of the meatal mucous membrane is indicated or necessary. The cautery loop provides adequate hemostasis. Should postoperative bleeding occur, it is controlled easily by an indwelling catheter for 24 to 48 hr.

The postoperative courses of these four young girls were certainly gratifying. They had very little discomfort even during the first few days and were completely symptom-free in 10 days. In all cases the appearance of the urethral meatus was normal, and we were able to pass 16 F. catheters with ease within 10 days following the procedure. To date, two to six months postoperatively, no strictures have occurred, and there has been no difficulty in urination.

REPORT OF CASES

Case 1.—N. S., a 5-year-old Negro girl, was admitted on Aug. 30, 1949, with dysuria of 10 months' duration, which was getting progressively worse. Her family had observed a "swelling" in her vulva, and spots of blood on her underclothes had been seen. Elsewhere the lesion had been treated with applications of silver nitrate without satisfactory results. Her past history was noncontributory as far as her present difficulty was concerned. A physical examination at birth had been recorded as showing no abnormality. At the time of admission a definite outpouching of the urethra was observed. It measured about 1.5 cm. in diameter and protruded about 0.75 cm. The lesion was inflamed, with areas of gangrene. In the center of this protruding mass the urethral orifice could be seen. A catheter was passed easily, and the urine from the bladder was found to be microscopically normal. Cystoscopic findings and an intravenous urogram were also normal. The lesion improved in appearance after hot sitz baths, and three days later the lesion was excised throughout its entire circumference with the cautery loop. In one week the patient was asymptomatic, and the urethral meatus appeared normal. When last seen, about six months after the procedure, the patient appeared normal, and no stricture was observed.

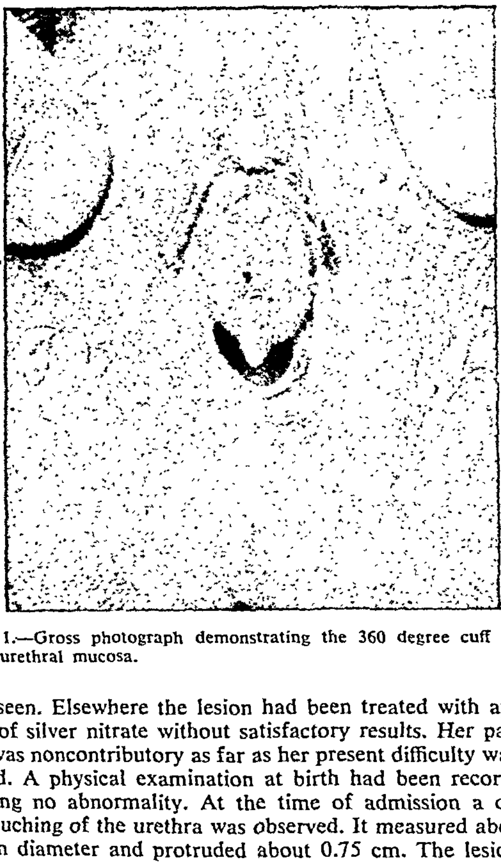

Fig. 1.—Gross photograph demonstrating the 360 degree cuff of prolapsed urethral mucosa.

[5] Hepburn, T. N.: Prolapse of the Female Urethra, Surg., Gynec. & Obst. 31: 83, 1920; Prolapse of the Urethra in Female Children, ibid. 44: 400, 1927.

Case 2.—J. S., a 5-year-old Negro girl, was admitted on Aug. 27, 1949, with the complaint voiced by her parents that she had a "swelling in her privates." According to her mother, this had started five days previously. The girl also had moderate pain on urination, and bleeding was observed at the urethral meatus. No previous treatment had been sought. She had been born at this hospital, and a routine examination at birth had disclosed no abnormalities. On examination it was noticed that the region of the urethral meatus was edematous, protruding, and inflamed. A catheter was passed easily through the center of this protruding mass, and the bladder urine was found to be normal. Again, cystoscopy findings and an intravenous urogram were normal. After hot sitz bath treatments the redundant tissue was excised without incident. This patient had dysuria for three weeks, but after that she was asymptomatic and the meatus had a normal appearance. When last seen, four months following the procedure, there was no evidence of a stricture.

Case 3.—E. T., a 7-year-old Negro girl, was admitted with the complaint of "bleeding from the privates" for five days. No previous trouble had been observed. The mother had noticed three days prior to admission an inflamed protruding mass in the child's vulva. Virtually no urinary symptoms had occurred. Examination revealed an inflamed protruding mass at the urethral meatus. Any manipulation of the lesion would cause bleeding. The urethral orifice was easily seen in the center of this mass, and a catheter was passed. The bladder urine was microscopically normal. No abnormality was revealed by cystoscopy or on the urogram. Excision of the prolapsed mass was done on the fourth day with minimal bleeding. After this the patient was clinically asymptomatic, and within 10 days the urethral meatus had an entirely normal appearance. At the last visit, six weeks later, the child had no symptoms and no evidence of stricture.

Case 4.—C. D., a 3-year-old Negro girl, was brought into the hospital because her parents had noticed "spots of blood" on her underclothes. This had been present for three days. The day prior to admission a physician had been consulted, and he made a diagnosis of an edematous and hemorrhagic hymen. No urinary symptoms were present. Examination revealed an inflamed and hemorrhagic mass protruding from the urethral meatus. Several small areas were gangrenous. The urethral orifice was identified easily. The bladder urine was microscopically normal, and cystoscopy findings and intravenous urograms were normal. Hot sitz baths were prescribed, and on the fourth day excision of the prolapsed urethra was done. There were no postoperative urinary symptoms, and the patient was discharged on the fourth postoperative day. When she was seen as an outpatient one week later, the meatus appeared entirely normal. At the last visit, about four weeks later, no stricture was observed.

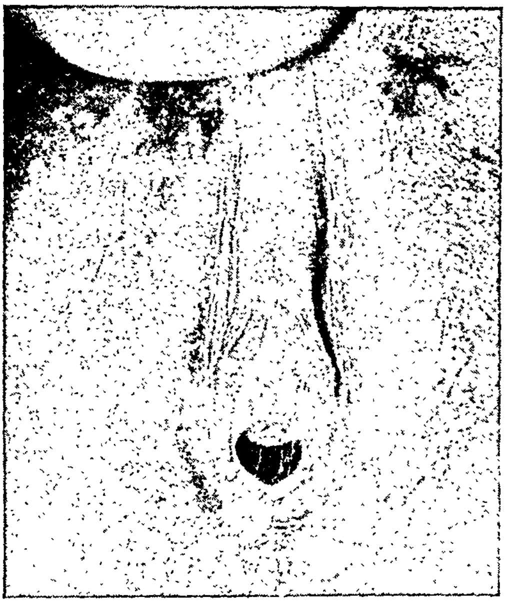

Fig. 2.—Urethral orifice six days postoperatively.

PATHOLOGY

There are no pathognomonic findings in the microscopic appearance of the tissue.[6] It is a picture of vascular engorgement with acute and chronic inflammation of the urethral mucosa and the underlying tissues. In many areas the vascular engorgement is extreme. The numerous telangiectatic spaces are similar to those seen in internal hemorrhoids. This fact is not surprising, for the same stress factors are present in the two conditions. A frequent pattern of small vascular channels lying vertical to the surface is also present. This is similar to many superficial granulomatous processes.

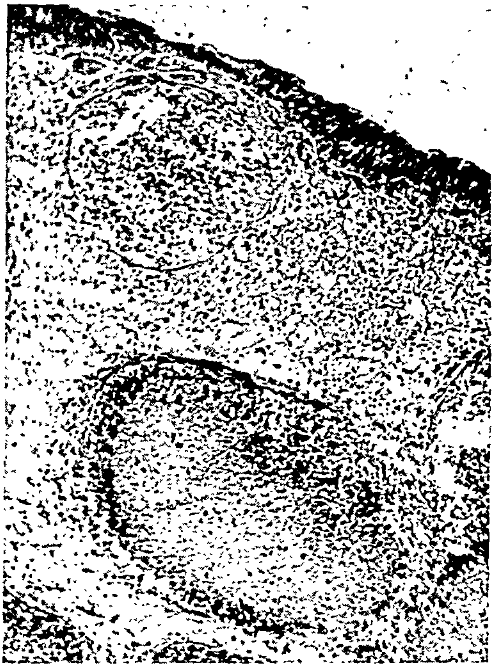

Fig. 3.—Photomicrograph showing the greatly dilated vessels and marked congestion and inflammation of the prolapsed urethra. × 120.

If it is assumed that the pouching-out of the mucosa was the primary change, all the vascular changes observed in our cases could well have been secondary to stress, interference with blood supply and return, and the infection of the prolapsed tissue.

SUMMARY AND CONCLUSIONS

Four cases of prolapse of the urethra in young girls are reported. Emphasis is placed on diagnosis and what we believe is an efficient method of treatment. Prolapse of the urethra in young girls, although heretofore not thought very common, is certainly not a rarity and seems more prevalent at an early age. Typical findings are bleeding from the lesion, a "mass" presenting at the urethral orifice, and varying degrees of dysuria. In our cases the prolapse occurred for the entire circumference of the urethral mucosa. Adequate treatment consists in total excision of the prolapsed portion. An indwelling urethral catheter may be used in cases of excessive bleeding. Sutures were not found necessary. The patients became asymptomatic early, and stricture formation has not been observed.

CLINICAL ASPECTS OF CORONARY HEART DISEASE

AN ANALYSIS OF 100 CASES IN PATIENTS 23 TO 40 YEARS OF AGE WITH MYOCARDIAL INFARCTION

M. M. Gertler, M.D., New York, Commander M. M. Driskell (MC), U. S. N.
E. F. Bland, M.D., S. M. Garn, Ph.D., J. Lerman, M.D., S. A. Levine, M.D., Boston
H. B. Sprague, M.D., Brookline, Mass.
and
P. D. White, M.D., Boston

In an attempt to solve some of the problems of coronary heart disease in young men and women, thereby gaining a better understanding of the disease as it occurs in older patients, a special project was established at the Massachusetts General Hospital, Boston, in 1946. Since then, 100 patients who had myocardial infarction prior to the age of 40 have been studied. In addition, 146 persons (average age 38), healthy at the time of the examination, were studied for purposes of comparison. This report is confined to the clinical aspects of coronary heart disease in the former group.

For many years it has been recognized that atherosclerotic changes in the coronary arteries are not concomitant with "old age" alone, and that such changes can be, and often are, found in young men and women in whom none of the other expected changes of old age can be demonstrated. Indeed, case reports of angina pectoris and myocardial infarction in persons less than 40 years of age have appeared in the medical literature with increasing frequency since Herrick's original report in 1912 of the clinical pictures of myocardial infarction correlated with the pathological changes of the coronary vessels in this condition.[1] But it is only recently that interest has centered in the younger age groups, and several excellent and detailed studies have been published.[2] Coronary heart disease has been reported in infancy [3] and as early as five years of age in cases of progeria.[4]

When the project was established it was decided that emphasis should be placed on the etiology of the disease as it related to familial tendency, biochemical and metabolic changes, body build, previous medical history, and physical findings. Furthermore, and in order to avoid coloring the results with the changes found in older people, it was decided that the patients to be studied must have experienced myocardial infarction prior to the age of 40, with an unequivocal clinical history and electrocardiographic evidence of such myocardial infarction; they must have been less than 50 years old when examined, and they must have experienced the last episode at least six months before the examination. In addition, the selected patients were to have "pure" myocardial infarction, uncomplicated by hypertension, peripheral vascular diseases, diseases of the collagen group, diabetes, xanthomatosis, or other recognized metabolic disorders.

The names of the first patients selected for evaluation were taken from the files of the Massachusetts General Hospital and from the records of cardiologists in the Boston area who were interested in this work. Later, in order to obtain a better cross section of the entire population, hospitals and cardiologists throughout the country were requested to submit the names of patients who met the requirements and who were willing to come to Boston for examination. Their splendid response is shown by the fact that 59 patients from all parts of the country east of the Rocky Mountains were examined.

During the examination the patients were admitted to the Massachusetts General Hospital for periods of approximately 24 hr., and the following studies were completed: history and physical examination, anthropometric measurements, biochemical determinations, and hormonal appraisal.

This paper is concerned principally with the clinical aspects of the patients studied, including the fluoroscopic and X-ray findings, electrocardiographic changes, physical examination, and that part of the medical history related to the preceding symptoms and those described by the patient at the time of the acute episode.

CLINICAL OBSERVATIONS

Sex.—A total of 100 persons (97 men and three women) were examined. The ratio of men to women in this series is essentially the same as that previously reported by Glendy, Levine, and White, i. e., 24:1.[5]

Age of Onset.—The average age of the 97 men at the time of the acute episode was 35.4 yr., of the three women 38 yr. The over-all span was 24 to 51 yr. The youngest patient examined was a 24-year-old intern who had experienced the episode one year previously.

5. White, P. D.: Heart Disease, ed. 3, New York, The Macmillan Company, 1944, p. 28.

Ethnic and Racial Origin.—The racial and ethnic groups common on the east coast were all represented in this series. The largest group (32) was of Scotch-English and Scotch-English-Irish origin; an additional 12 were second or third generation Irish; two were Negroes.

Of the series, 27 were Jewish, six were Italian, two were French, one was Armenian, and one was Syrian. Thus, persons of Mediterranean or east Mediterranean origin comprised 37% of the group—a proportion well in excess of their representation in the areas from which the sample was drawn.

Occupation.—As concluded in reports of a similar nature, occupation does not seem to be causally related to the development of coronary heart disease.[6] Nevertheless, the present series reveals an overloading of certain occupational categories: the managerial (38%), executive (11%), professional (14%), and skilled-labor positions (37%) comprise a disproportionate section even among patients referred by the Veterans Administration. Thus, in this series, as in others, certain types of occupation do predominate.[7]

Of the group, 29 changed their occupations in order to avoid heavy labor, lifting, excessive walking, and the like. One, an enlisted man at the time of attack, has regressed to a life of complete inactivity, which includes 12 hr. of sleep per day. Six of the 29 have no regular activity but work sporadically at odd jobs and part-time employment.

TABLE 1.—*Age and Sex Distribution*

Age at Onset	Men	Women	Total
20-29	8	0	8
30-34	28	0	28
35-40	61	3	64

TABLE 2.—*Daily Tobacco Intake of the Coronary Disease Group and the Control Group*

	Cigarettes	Cigars	Pipes*
Coronary group	19.4 ± 1.6†	0.17 ± 0.10	0.85 ± 0.29
Control group	13.8 ± 1.1	0.25 ± 0.09	0.56 ± 0.16

* Each pipeful was considered to be 0.1 oz.
† Mean ± standard error.

It appears likely that this is an occupational expression of mesomorphy, and hence there may be no definite causal relationship between occupation and coronary heart disease.[8]

Tobacco and Alcohol.—Data relating to the weekly alcohol intake and the daily tobacco intake of both the coronary disease group (prior to the episode) and the control group are summarized in tables 2 and 3.

On the average, the coronary disease group consumed more tobacco than the control group. The total cigarette intake of the coronary disease group was significantly greater ($p = 0.02$) than that of the control group.

In absolute quantities, the control group consumed more alcoholic beverages than the coronary disease group. However, the coronary disease group ingested significantly more alcohol in the form of scotch, gin, and bourbon ($p = 0.05$) than did the control group.

TABLE 3.—*Weekly Alcohol Consumption of the Coronary Disease Group and the Control Group*

	Beer	Wine	Liquor
Coronary group	*25 ± 4.87**	*2.9 ± 1.14*	*6.4 ± 1.27*
Control group	32 ± 5.08	2.5 ± 0.56	3.6 ± 0.69

* Mean ± standard error.

Data referring to the number of persons in each group who (*a*) refrained from ingesting alcohol and smoking and (*b*) ingested alcohol and smoked are summarized in tables 4 and 5.

Not only did the smokers in the coronary disease group smoke more than did the smokers in the control group, but there were proportionately more persons in the coronary disease group who smoked. There was no difference in the proportion of persons in both groups who ingested alcohol.

These data do not give any information on the effect that smoking may have on the cardiovascular system, as has been provided by several authors.[9] It should not be inferred from these results that cessation of smoking will benefit or prevent coronary heart disease.

Incidence by Month, Season, and Time of Day.—There is a greater absolute incidence of myocardial infarction in the fall and winter months, which, on statistical analysis, is significant ($p = 0.01$). Thirty episodes occurred in the fall, 31 in the winter, 19 in the spring, and 20 in the summer. The majority of attacks listed for fall or spring occurred during the late fall or early spring months, which again demonstrated the proclivity of infarctions to occur during cool or cold weather. Of those that occurred during the summer months, 11 of the 20 were directly related to heavy work or exercise, such as playing tennis.

TABLE 4.—*Smokers and Nonsmokers in the Coronary Disease Group and the Control Group*

	Smokers	Nonsmokers
Coronary group	81	9
Control group	107	32

Chi square = 8.94 (significant $p > 0.01$)

The majority of episodes occurred during the hours of increased activity after meals, with the greatest incidence in the midafternoon. On the average, the episodes occurred shortly after the midday meal. The majority of acute episodes (62%) occurred between the time of waking and shortly after the noon meal, the time of day during which most men are active.

Preceding Complaints.—Each patient said he had one or more symptoms; thus the symptom of angina pectoris was elicited in 41 instances, dyspnea in 22, indigestion in 20, fatigue in seven, and nervousness in four. In 15 in-

stances precordial pain was associated with radiation of pain—to one or both arms in 14 instances and to the left shoulder in one instance. Of the 64 patients who gave a history of complaints prior to the incident (angina, substernal oppression, and the like), eight said that the complaints had been present longer than one year, three had them as long as four years, and one as long as five years. The 52 remaining patients had noted some form of distress (presumably other than cardiac) less than one year, usually only a few months, preceding the attack. Three had had tightness in the chest on exertion only three days before the acute attack, which may represent a partial occlusion of one of the coronary vessels, progressing to complete occlusion and infarction on continued activity.

Excessive sweating	8	Choking	1
Collapse	7	Faintness	1

Complaints at Onset of Myocardial Infarction.—Only four of the 100 patients had no pain during the attack, but those four had other complaints, such as dizziness, nausea, and vomiting. The pain, when experienced, lasted seven hours for the group (with a range of 20 min. to 72 hr.). The pain was severe in 62 instances, moderate in 32 instances, and slight in four instances. The findings are summarized in table 6.

Walking	21	Driving or riding	3
Manual labor	18	Getting out of bed	3
Sleeping	11	Eating	2
Performance of professional duties	8	Running	1
Exercising	6	Dressing	1

In 64 instances the pain was not confined to the precordium but radiated elsewhere to one or more regions. This is summarized in table 7.

Activity at Onset.—Of the 18 patients listed as having the episode while performing manual labor, nine experienced it while engaged in some type of work to which they were not accustomed. In two of these instances (see No. 12 and No. 83, Table 9) unusual excitement superimposed on the unusual activity at the time probably was an additional factor. A total of 21 persons engaged in some type of activity, exercise or otherwise, that required greater work on the part of the heart than did their usual daily routine. It is thought that this may be a factor in the development of infarction of the myocardium.

Additional information was provided on the question of the relationship of effort to coronary heart disease. From approximately 7:30 a. m. to 7 p. m. the observed episode rate was five and one-half per hour; for the remaining period of the day, which may be considered a period of "inactivity or basal rate," the rate of occurrence was two and four-fifths episodes per hour. Accordingly, one-half as many episodes are apt to occur during periods of rest or "inactivity" as during periods of activity. These points will be reconsidered at the conclusion of this paper.

Fluoroscopic and X-ray Findings.—Ninety-seven of the patients (the men) had roentgenographic examinations; these men were examined with the fluoroscope, and 7 ft. x-rays were made of the posteroanterior view. Two patients had left ventricular aneurysm with paradoxical pulsations. In one of these the infarction had occurred nine years previously, and in the other it had occurred one year before. Ten patients presented fluoroscopic evidence of diminished pulsation along the lateral margin of the left ventricle, which the roentgenologist interpreted as a probable area of infarction with scarring. These findings are much lower than those reported by other authors.[10]

TABLE 9.—*Episodes Occurring During Unaccustomed Activity*

Electrocardiographic Observations.—Using the three standard limb leads, three unipolar limb leads (aV_R, aV_L, aV_F), and six unipolar precordial leads (V_1 through V_6), evidence of infarction was demonstrated in every case, including one of 10 years' duration and another of 21 years' duration. There was a total of

Biochemical Observations.—These observations are considered in other publications in greater detail.[11] The levels of serum cholesterol (free, esters, and total), uric acid, and phospholipids are listed in table 11. It is to be noted that the mean value of each variable in the coronary disease group exceeds the mean value of each variable in the control group. The mean serum lipid values and serum uric acid values of both groups are shown in table 11.

TABLE 11.—*Mean Values of Serum Lipids and Serum Uric Acid in the Coronary Disease Group and the Control Group*

	Coronary Group	Control Group
Free cholesterol	110.4 ± 3.9	99.7 ± 2.3
Esterified cholesterol	176.7 ± 5.5	121.7 ± 2.6
Total cholesterol	286.5 ± 6.6	224.4 ± 3.5
Phospholipids	316.4 ± 6.7	299.3 ± 3.3
Uric acid	5.13 ± 0.11	4.64 ± 0.06

TABLE 12.—*Physical Groupings in the Control Group and the Coronary Disease Group*

	Control Group, %	Coronary Disease Group, %
Endomorphy	29	26
Mesomorphy	19	42
Ectomorphy	22	7
Others	30	25

Body Build.—The coronary disease group was predominantly mesomorphic (muscular) and contained very few ectomorphic (linear) persons. These observations are given in detail elsewhere,[12] but the results are summarized in table 12 for the 97 men patients with coronary heart disease and for the 146 controls.

The difference in height and weight between the control group and the coronary disease group is discussed in greater detail in a separate publication.[13] It is sufficient to say here that the coronary disease group was 5 cm. shorter than the control group; the average height for the coronary group was 171 cm., and the average height for the control group was 186 cm. The average weight for the coronary group was 177 lb. (80,300 gm.), while the average weight for the control group was 171 lb. (77,500 gm.).

Physical Examination.—In the majority of cases the physical examination was remarkably unrevealing. This is consonant with other published data.[2a]

Hospitalization.—Seventy of the patients were hospitalized for an average of six and one-fifth weeks at the time of the acute episode and remained inactive for an average of three months after the hospitalized period. Twenty-one patients were treated at home for a similar period. The episodes of nine patients went unrecognized or ignored during the illness. No attempt was made to evaluate the methods of treatment carried out during the acute illness.

TABLE 13.—*Present Complaints in Ninety Patients of the Coronary Disease Group*

Angina pectoris	36	Fatigue	4
Dyspnea	16	Dizziness	2
Limitation of activity without complaints	24	Crippled by gout	1
Palpitation	9	No complaints	18

Prognosis.—Ten patients (nine men and one woman) discussed in this series have died since examination, all presumably from recurrent infarctions; six of these deaths occurred after one additional infarction, three after two additional infarctions, and one after three additional infarctions. Twenty-six others have had additional infarctions, including two who have had a total of three infarctions, and one, a physician, who has had a total of four infarctions and who still carries on a limited practice.

Eighteen of the patients have not restricted their work or activity in any way and have no complaints referable to the cardiovascular system at this time. Twenty-four have voluntarily limited their work or exercise and likewise have no cardiovascular complaints. The remaining 58 patients, except for one man who is crippled by gout, have angina of effort, dyspnea, or a combination of the complaints listed in table 13. Two are heavy users of nitroglycerine, one taking approximately 300 tablets per week.

At this writing (Dec. 1, 1949) the 90 living patients have survived an average of 3 yr. and 11 mo. since the date of the initial acute episode. One man is alive 22½ years after the original episode, though crippled by gout at this time. The 10 patients who have died since our original examination survived an average of three and one-half years, including one who remained alive and active more than 11 years. In the latter group, eight of the 10 had preceding complaints for periods of two months to five years, consisting of mild to severe dyspnea and angina associated principally with effort. Thirty-six patients who had prior complaints, such as angina, dyspnea, or palpitation, continued to have these same complaints frequently and more severely after the infarction. Sixteen patients who listed some complaints beforehand are now symptom-free. The majority of these patients, however, have curtailed their activities and do not extend themselves to the point of inducing angina pectoris, dyspnea, or other symptoms.

COMMENT

The clinical examination corroborated the well-known observations of the paucity of clinical findings in persons who have experienced myocardial infarction. One of the most striking observations made was that these men appeared older than their chronological age. With very few exceptions, each person appeared to be at least a decade older than his chronological age. This raised the question that has been considered by Carrel[14] and others: How does the rate of living affect the longevity of the person? These people are mostly mesomorphs, and, being mesomorphs, the energy expended in foot-pounds per unit of day is probably far greater than that expended by ectomorphs, who do not experience the disease with the same frequency.

Cardiac enlargement was ascertained clinically in only five patients, while 22 instances of enlargement were reported by x-ray examinations. Fluoroscopic examination did not reveal more than 10 instances of paradoxical pulsations and diminished pulsations. This number is far less than reported by others; no explanation is apparent for this difference.[9a,b]

In this series 36 patients had no premonitory symptoms prior to the acute episode. Of the 64 who had premonitory symptoms, 41 had angina pectoris, and 20 (all men) thought they had indigestion. The history in the latter group was not definitive enough to warrant a diagnosis of angina pectoris. The number of patients who had premonitory symptoms (64%) is greater than that (50%) reported by Yater and colleagues in their series.[2a]

Ninety-six per cent of the patients experienced substernal or precordial pain immediately prior to the acute episode of myocardial infarction. This pain was severe in 62 patients, moderate in 32, and slight in two. Such a rating is obviously inadequate, for the threshold and interpretation of pain vary in different persons; therefore, any subjective rating is ineffective under optimal conditions. The locations to which the precordial pain radiated were not the classical regions, for in only 29% did the pain radiate down both arms. Furthermore, in 32 instances no pain was observed to radiate from the precordial region.

The question of relationship of effort to coronary heart disease will be discussed in greater detail in a forthcoming publications.[15] Only 11 instances of acute coronary occlusion occurred during sleep. In 21 instances the episodes occurred while the men were engaged in some activity other than their usual occupation. These facts are not meant to suggest that there is a direct causal relationship between effort and myocardial infarction, for these data will not permit such a conclusion. However, it is believed, on the basis of the evidence presented here, that activity, usual or otherwise, may precipitate acute myocardial infarction.

These 100 patients represent a cross section of occupations, from laborers to professional workers. There was a paucity of farmers in this group, for the study was conducted in an urban area where farmers would not be apt to be referred. There is insufficient evidence to consider here the difference of incidence of coronary heart disease in urban and in rural populations.

Coronary episodes occur significantly more frequently in the late fall, winter, and early spring. It is noteworthy that the majority of acute episodes of coronary heart disease occurred during the time of day when most people are engaged in productive activity. Again, this does not prove that there is a direct causal relationship between effort and coronary heart disease, but it is reasonable to conclude that activity may influence the rate of occurrence of the coronary episodes.

The clinical clues to the etiology of coronary heart disease are few but important. Each clue suggested by these observations must be carefully studied and coordinated. The challenge of coronary heart disease must be met by continued effort and study, difficult and unrewarding as it may appear; each additional clue may bring us closer to a final solution of the etiology of coronary heart disease.

SUMMARY

One hundred people (97 men and 3 women) who had experienced myocardial infarction prior to the age of 40 were studied under hospital conditions for periods varying from 24 to 72 hr.

The average age at the time of the first episode was 38⅕ yr. The average survival time at the time of this report is 3 yr. and 11 mo., with a range between nine months and 22½ yr. Thirty-two per cent of the persons in this series were of British Isles mixture, and 27% were Jews. There is a suggestion of seasonal predilection for myocardial infarction, which is confirmed by statistical examination.

Sixty-four per cent of the patients had symptoms prior to the acute attack. Of these, 41 % were classified as angina pectoris. In 96% of the cases, substernal and/or precordial pain immediately preceded the onset of the acute coronary episode. Electrocardiographic, x-ray, and fluoroscopic examinations aided in diagnosis.

The coronary disease group was characterized by (*a*) mesomorphic body build, and (*b*) increased levels of serum cholesterol and serum uric acid, in contrast to the normal population. The coronary disease victims were shorter and wider, with increased anteroposterior chest diameter compared with a control group. They did not, however, weigh more on the average than those in the control group.

There appears to be a definite relationship between the incidence of coronary episodes and the time of day. In 62% of the instances the initial myocardial infarction occurred approximately between 7:30 a. m. and 7 p. m. (or during the average working day). It is thought that activity is not directly related to the myocardial infarction, although it may accelerate previously existing coronary heart disease into myocardial infarction.

MEPHENESIN IN TREATMENT OF TETANUS

RESULTS OF ORAL ADMINISTRATION IN THREE CASES

Truett C. Boles, M.D.
and
James H. Smith, M.D., Miami

Mephenesin (3-ortho-toloxy-1,2-propanediol) is a synthetic compound which exhibits profound muscle-relaxing properties, and offers a new approach to the treatment of spastic and neurological disorders. The ability of mephenesin to act on the abnormal neuromuscular mechanisms responsible for muscle spasm, spasticity, rigidity, tremor, and dyskinesia has been demonstrated by Schlesinger and associates,[1] by Gammon and Churchill,[2] by Berger and Schwartz,[3] and by others.[4]

Control of the spasms of tetanus, treated by parenteral administration of mephenesin, has been reported in several cases.[5] The oral administration of mephenesin in tetanus has not been extensively reported.[6] It is the object of this paper to present three cases in which tetanus was treated successfully with oral doses of mephenesin in combination with phenobarbital sodium.

REPORT OF CASES

Case 1.—S. H., an 8-year-old Negro schoolboy, was admitted to Jackson Memorial Hospital on June 1, 1949, after an illness of four days' duration. The admission complaints consisted of inability to open his mouth, inability to sit or stand, difficulty in swallowing, and intermittent convulsive seizures of two days' duration. The onset of the illness was accompanied by a temperature elevation to 100 F. rectally. Jerking movements of the extremities had been observed since the onset of the illness. The patient had had generalized convulsive seizures two days prior to hospitalization. He had been able to take only liquids by mouth owing to severe trismus. There was no history of unconscious episodes. The history further revealed that two weeks prior to admission the patient had stepped on a splinter of wood. The fragment was removed and the wound cleaned, and it had apparently healed normally. The patient had been in good health almost all his life and had never contracted any of the childhood diseases. He had had no immunizations.

Physical examination revealed a well-developed but undernourished Negro boy with a blood pressure of 106/80, a pulse rate of 130 per minute, a respiration rate of 20 per minute, and a temperature of 99.6 F. He was unable to sit or stand owing to spastic musculature. Typical risus sardonicus facies with severe trismus, nuchal rigidity, spastic abdominis rectus muscles, and severe spasm of the entire erector spinae group of muscles were noted. The skin was moderately dehydrated, and the heart and lungs were normal. Abdominal examination could not be done owing to spasm. Deep and superficial tendon reflexes were hyperactive. The left heel revealed a healed, nontender, nonfluctuant puncture wound without evidence of peripheral spread of infection from the area. The results of laboratory tests, including urinalysis, complete blood cell count, Kahn test, spinal fluid tests, and sickle cell preparation, were within normal limits.

Course.—The patient was placed in an isolated, quiet room with special nurses. Mild muscular contractions were observed whenever his body was stimulated. Muscular relaxation was obtained initially with tribromoethanol by rectum. Intravenous administration of fluids was started, and 60,000 units of tetanus antitoxin was given intramuscularly. Approximately six hours following admission it was necessary to insert a rubber airway, so that suctioning of tenacious mucus could be carried out. Approximately 11 hours following admission a plastic stomach tube was passed, and two mephenesin tablets (0.5 gm.) were crushed in water and given by tube. An additional 450,000 units of tetanus antitoxin was given by intravenous drip, and surgical excision of the wound of the left heel was carried out. Since the patient had no abnormal reaction to the test dose of mephenesin, one tablet (0.25 gm.) every four hours was prescribed. Since admission the patient had been having muscular spasms lasting from 20 to 30 sec. with boardlike rigidity of the abdomen.

Approximately 12 hours after institution of mephenesin therapy, in combination with phenobarbital, the patient was resting quietly, arousing only when intramuscular injections of penicillin were administered. Tube feedings were retained well. The patient had to be catheterized on two occasions during the first 24 hours of hospital stay because of moderately severe distention of the bladder.

By June 3 the patient's improvement was almost dramatic. He began taking fluid and water by mouth and was able to open his mouth fully. On June 4 be was able to take semisolid food by mouth and began turning himself in bed. Because of some persistence of the tonicity and spasticity of the abdominal muscles, the dose of mephenesin was increased on June 6 to one and one-half tablets (0.375 gm.) every four hours. This increase in the dose seemed to render the patient less hyperexcitable to stimuli, but the spacticity of the abdominal musculature persisted.

The patient continued to improve generally for the next three days, being able to eat and drink almost normally and to move about in bed at will, and he was apparently comfortable. On June 9 the mephenesin medication was discontinued. Within 12 hours the patient was in opisthotonos with spastic musculature. The treatments were resumed, and the response, as before, was good. On June 10 the patient was transferred to another hospital for convalescent care.

Case 2.—G. K., a 6-year-old Negro boy, was admitted to Jackson Memorial Hospital from the emergency room on Sept. 1, 1949, complaining of difficulty in opening his mouth. He had sustained an injury to his right knee 11 days prior to admission, on Aug. 21, 1949. The laceration was sutured by his local physician but no tetanus antitoxin was given. On the day before admission the patient complained of inability to open his mouth. On the day of admission he refused to sit up or eat and complained of pain in his back. He had three generalized convulsions with marked opisthotonos while in the admitting room. The past history revealed no immunizations and measles and chicken pox in 1948.

Physical examination revealed a 6-year-old well-developed and well-nourished Negro boy who was in marked opisthotonos with spastic musculature, a blood pressure of 110/76, a pulse rate of

140 per minute, and a temperature of 100.2 F. rectally. While the patient was being observed, he had several tonic and clonic generalized muscular spasms with his legs flexed upon his abdomen, neck hyperextended, and back arched. He was alert and very apprehensive and complained of severe abdominal pain prior to the spasms. He had marked trismus and spasm when stimulated with a tongue blade in his mouth. He was able to open his mouth about 1 in. (2.5 cm.). The chest and heart were normal on examination. The abdomen showed marked spasm of abdominal muscles. The right leg presented an infected swollen wound below the right knee with necrotic purulent debris around an old suture line. The reflexes were all present, equal, and hyperactive.

Course.—Initially the patient was given 125 mg. of isoamylethylbarbituric acid (amytal®) intravenously. Surgical débridement of the infected wound was done, and a lumbar puncture revealed normal spinal fluid. An intravenous injection of 5 per cent dextrose in distilled water with 400,000 units of tetanus antitoxin was started after a negative skin test with horse serum. A plastic stomach tube was introduced, and 3 fluidrachms (12 cc., 1.2 gm. of the drug) immediately and 1 fluidrachm (4 cc., 0.4 gm.) of elixir of mephenesin every four hours was started through the tube. After tolerance and reaction to mephenesin were determined, the dosage was increased to 2 fluidrachms (8 cc., 0.8 gm. of the drug) every four hours at the end of the first 24 hours and to 3 fluidrachms every four hours at the end of 36 hours.

Forty-eight hours after admission, on Sept. 3, the intravenous fluids and medications were stopped and tube feedings were started. The patient was relaxed and moved his extremities freely by this time. Though the muscles were not in spasm, he still lay with his back and neck hyperextended. He continued to have occasional generalized spasm with stimulation.

On Sept. 4 the mephenesin dosage was changed to 2 fluidrachms every two hours, since the muscles of his extremities became very tense between the third and fourth hour following mephenesin medication. Thirty milligrams of sodium phenobarbital every four hours was added to the intratube medicaments. By Sept. 5 the mephenesin had been increased to 3½ fluidrachms (14 cc.) every two hours. The patient was now moving in bed without assistance, though the muscle tone of his extremities was increased. He was taking fluids by mouth without difficulty.

During the next several days the patient was free of spasms, but his abdomen became distended; the condition subsided after manual removal of a fecal impaction. The patient continued to lie with his head and back hyperextended. The mephenesin was increased to 4 fluidrachms (16 cc., 1.6 gm. of the drug) every two hours in an attempt to relax the back muscles, which seemed to be moderately spastic. No relief of the spasm was obtained. The patient was comfortable in this position and could roll from side to side.

Mephenesin treatment was discontinued on Sept. 12 to test the apparent therapeutic response. For the two preceding days the patient had been completely relaxed and responsive. Within 12 hours he was again in marked opisthotonos, complaining of severe pain in his back and extremities. Mephenesin administration was resumed.

On Sept. 13 the patient began taking soft food by mouth, and the tube feedings were discontinued. By Sept. 16 he was ambulatory with assistance; phenobarbital was discontinued, and the mephenesin dosage was changed to one and one-half tablets (0.375 gm.) every four hours. During the next two days the patient became more alert and active. On Sept. 26 he was ambulatory and played about the ward without difficulty. He was walking without difficulty or rigidity with the exception of a slight limp as he favored his healing right leg. The confusion and slow cerebral function which marked the previous two weeks' convalescent period had subsided. Because of the persistence of a temperature of 100 to 101 F. rectally, penicillin was administered throughout the initial period of treatment and was continued for 10 additional days following the return of the temperature to normal. Mephenesin therapy was discontinued, and the patient was discharged on Sept. 30, 1949, without residual findings.

CASE 3.—L. R., a 2½ year old Negro boy from the island of Bimini, was admitted to Jackson Memorial Hospital on Sept. 27, 1949, with the diagnosis of tetanus. About nine days prior to admission he fell, cutting his right knee on a piece of glass. The wound was sutured, and the patient was given penicillin but no tetanus antitoxin. The day prior to admission irritability developed, and the patient failed to play as usual. With the onset of muscular rigidity he was transferred to our hospital. The past history revealed that the child had always been in good health and had had no immunizations.

Physical examination on admission revealed a well-developed, well-nourished, but acutely ill Negro boy in opisthotonos, who had generalized tonic spasms when disturbed by external stimuli or when attempting to expectorate accumulated mucus from the pharynx and throat. Marked trismus prevented complete examination of the mouth and pharynx; the skin was hot and dry, and the right leg presented an infected area measuring 4 by 5 cm. below the right knee. The chest, heart, and abdomen, except for spastic abdominal muscles, were normal on examination. The blood pressure was 115/60, the pulse rate 152 per minute, the respiration rate 36 per minute, and the temperature 101.6 F. rectally.

Course.—The patient was placed in a darkened room with special nurses. He was given immediately 60 mg. of isoamylethylbarbituric acid intravenously to obtain complete relaxation. The wound was débrided by wide surgical excision by the surgical service. Intravenous administration of fluids was started with 5 per cent dextrose, and a plastic tube was placed into the stomach through the nose. The spinal fluid was within normal limits, and a complete blood cell count showed slight anemia. The isoamylethylbarbituric acid injection was repeated as the patient began to arouse. Four hundred thousand units of tetanus antitoxin was added to the intravenous fluids, and 40,000 units was infiltrated around the débrided wound.

Four hours after admission 1 fluidrachm of elixir of mephenesin was added through the tube to test the sensitivity of the patient to the drug. With no apparent reaction to the drug, the patient was given 3 fluidrachms initially and 1 fluidrachm (4 cc.) every two hours through the stomach tube. During the next 18 hours he received a total of 520 mg. of barbiturates in addition to the above medicaments to keep him relaxed. Large accumulations of mucus in the pharynx, which caused convulsions through stimulation, made this sedation necessary. An antihistaminic and penicillin were also prescribed.

On Sept. 28 the mephenesin was increased to 2 fluidrachms every two hours, the phenobarbital to 60 mg. every four hours, and formula feedings were started through the stomach tube. The intravenous fluids were discontinued. The patient was well relaxed but continued to have slight spasms during the day when he aroused from his sedation. The patient's temperature began to spike, and the patient was treated symptomatically with salicylates and alcohol sponges.

On Sept. 30 a diarrhea developed, but it subsided after the sugar was taken from the tube feedings. The patient continued to be satisfactorily sedated and roused at intervals with occasional spasms. He received a transfusion of 250 cc. of whole blood. After a very restless night the mephenesin was increased to 3 fluidrachms every two hours, and the phenobarbital was increased to 90 mg. every four hours. The patient roused frequently during the following day and took sips of water without difficulty.

The patient was continued satisfactorily on this regimen for several days with an average of 10 to 12 mild generalized muscular spasms. He lay with his head in extreme extension and with his back arched, but the muscles involved did not seem spastic in that he could be moved and flexed easily. All the muscles were relaxed except the abdominal muscles, which remained tense during the entire acute stage.

On Oct. 3 the patient had a mild generalized urticarial rash, which was transitory. During the entire acute stage large amounts of mucus accumulated in the pharynx, which was freed by suction and frequent coughing. By Oct. 11 the persistent spiking temperature had returned to normal, and the patient was becoming more active.

The dosage of phenobarbital was gradually decreased to 30 mg. every six hours by Oct. 18. Three days later the patient was taking all food and medicaments by mouth and began talking and jabbering to himself. He was entirely free of spasms.

On Oct. 24 the mephenesin dosage was changed to four capsules (1 gm.) every four hours, and the process of teaching the child to walk again was started. At first he was very rigid, but within three days he was walking with support. Mephenesin was discontinued on this date. During the remaining two weeks in the hospital, the patient became more alert and cheerful. He was treated for ascariasis on two occasions before his discharge, on Nov. 10, 1949. He had no residual of stiffness or spasm on discharge.

COMMENT

An accurate evaluation of the effectiveness of various forms of therapy is extremely difficult, since cases of tetanus vary widely in many respects. However, there are certain general points in the therapy of tetanus which are universally agreed upon, namely, that the control of the spastic, tonic, rigidity state is essential to a beneficial result. By its effectiveness in controlling the spasticity and tonicity of tetanus without toxic manifestations and through its ease of administration, reducing the medical and nursing care, mephenesin has proved in our cases to be a valuable and effective adjunct to the therapy of this disease entity.

From the standpoint of effectiveness, we obtained in all cases adequate muscular relaxation. All muscles were relaxed and free of spasticity with the exception of the abdominal muscles, which remained moderately tense on maintenance dosages of mephenesin. The patient preferred to lie on the side with the back and neck slightly hyperextended, but there was no apparent resistance or discomfort to flexion or movement of the back. The effective dosage of mephenesin necessary for the control of spasm varied in all cases. When either the elixir or the tablet was used, the dosage was gradually increased until therapeutic effect was achieved. When mephenesin was combined with phenobarbital, the convulsions were controlled within a period of 24 to 48 hours following admission. Maintenance doses of phenobarbital never exceeded the amount necessary to produce light sleep, from which the patient easily could be aroused. The daily maintenance dosage of mephenesin for satisfactory muscle relaxation was 2.25 gm. in the first case, 19.2 gm. in the second, and 14.4 gm. in the third. We found that administration of the drug at two hour intervals was more effective in maintaining adequate muscle relaxation.

In a hyperexcitable state any medication which minimizes the amount of patient trauma is efficacious. The drug was administered through a flexible plastic stomach tube, obviating trauma such as is caused by repeated intramuscular and intravenous medications. The plastic tubes produced far less local trauma and irritation than the conventional rubber stomach tubes and could be left in place during the entire course of treatment.

We feel that mephenesin, by its ability to produce adequate muscular relaxation early in the disease process, substantially reduced the special medical and nursing care previously required in such cases.

In our cases we observed no toxic manifestations from mephenesin, despite the use of rather large dosages. Hematuria, anemia, leukopenia, respiratory depression, lassitude, and abdominal distention, all toxic signs seen following the use of mephenesin parenterally, were not observed when the oral route of administration was used.

Realizing that no definite conclusions can be drawn from such a small number of cases, we do, however, feel that our results warrant further investigation of this drug as a valuable adjunct to the therapy of tetanus.

VALUE OF CHOLESTEROL ESTERS IN DIFFERENTIAL DIAGNOSIS OF JAUNDICE

Joseph C. King, M.D.
and
Matthew Taubenhaus, M.D., Chicago

The presence of jaundice in a patient is a distinct concern to the clinician. He is confronted at the outset with its medical or surgical implications. For the differentiation of this jaundice, a number of clinical and laboratory methods are available; of these, the cholesterol ester fraction has been of particular interest to us.

In a discussion of the subject, Sidney A. Portis,[1] on the basis of his clinical observations, remarked that in obstructive jaundice the cholesterol esters are often diminished before any other liver function tests give abnormal results. A review of the literature revealed a number of contradictory statements on this matter.

The significance of a low cholesterol ester ratio of the serum in cases of parenchymatous jaundice has been well established.[2] It has been generally agreed that the liver cell esterifies cholesterol and that injury to the liver cell or decrease of its function interferes with this activity.[3] A low cholesterol ester content may, therefore, be due to inability of the hepatic cell either to esterify cholesterol or to release it into the blood stream.[4] In obstructive jaundice, however, a high total cholesterol with a relative increase of the ester ratio is frequently expected.[5] Only in later stages of biliary obstruction, as the liver cell becomes more and more damaged by the obstruction or by infection, do the esters begin to fall and reach values observed in parenchymatous jaundice, according to many authors.[6] This phenomenon has been studied experimentally by Hawkins and Wright [2h] and others.[7]

The cholesterol ester ratio in early stages of jaundice has been used as one of the diagnostic criteria for the differentiation between parenchymatous and obstructive jaundice.[8] It occurred to us that some cases of proved obstructive jaundice exhibited low cholesterol ester values in relatively early stages of obstruction, without any pronounced changes in other liver function tests. We decided, therefore, to analyze such cases, in order to evaluate the frequency and clinical significance of this phenomenon.

From the Department of Medicine, Michael Reese Hospital.

[1] Portis, S. A.: Diseases of the Digestive System, ed. 2, Philadelphia, Lea & Febiger, 1944, p. 345.

MATERIALS AND METHODS

Sixty-one cases observed on the surgical and medical services of Michael Reese Hospital during the past two years provided the material for this study. The diagnosis was established by clinical histories, physical findings and either surgical exploration or autopsy. In 15 cases either liver biopsies or specimens obtained at autopsy were examined histologically. The cholesterol and its esters were determined by the method of Schoenheimer and Sperry.[9] The methods for the other liver function tests were the same as those used routinely in Michael Reese Hospital. The cases were analyzed according to the cause of obstruction: (1) those due to biliary calculi and benign stenosis and (2) those due to neoplasms of the bile ducts or surrounding structures.

RESULTS

Case histories and duration of jaundice are not included in the tables so that extensive tabulation is avoided. Of the 42 cases of obstruction due to calculi or benign stenosis, six (15 per cent) showed an abnormally high total cholesterol (table 1). In 18 cases (42 per cent) the cholesterol ester ratio was low. The distribution according to the actual values is evident from the table. Comparison of the results in the other liver function tests in this group except for the serum bilirubin test indicates that only the results of the alkaline phosphatase test were abnormal in a number of cases approximately equal to those which showed abnormalities of the cholesterol esters (table 2). This elevation of phosphatase has generally been assumed to represent an indication of biliary obstruction. The other liver function tests used to assess the liver cell damage show abnormal values in a much lower percentage of the cases. This indicates clearly that there are a considerable number of cases in this group which show low cholesterol ester values, with normal values in the other liver function tests.

TABLE 1.—*Results of Total Cholesterol and Cholesterol Ester Tests*

	Cause of Obstruction			
	Stones and Stenosis		Carcinoma	
Liver Function Test	No. of Cases	Percentage *	No. of Cases	Percentage *
Total cholesterol, mg. per 100 cc. (normal, 120-300)				
50-120	3	7	0	0
121-300	33	78	13	68
301-400	4	9	0	0
401 plus	2	6	6	32
Cholesterol esters, per cent (normal, 61-74)				
0-10	0	0	1	5
11-20	1	2	3	15
21-30	3	7	0	0
31-40	3	7	5	25
41-50	4	9	2	10
51-60	7	17	3	15
61-70	22	52	4	20
71-80	2	6	1	5

* Percentage figures are approximate.

An analysis of our material reveals that there is a definite correlation between the duration of the icterus and the low cholesterol ester level. Of 26 cases of biliary obstruction due to biliary calculi or stenosis in which the jaundice was noticed for seven days or less, only one showed an elevation of the total cholesterol. Three of these patients showed low cholesterol esters although the other liver function tests gave normal results in each instance. The first patient obviously had a chronic hepatic disease secondary to chronic cholecystitis, with the acute episode being caused by a stone at the ampulla. Another patient had liver disease evidently of longer duration, as shown by the autopsy findings. The third patient also had extensive chronic liver disease after calculi. The other patients in this group, all exhibiting normal cholesterol ester values, had an acute onset without a history or pathological evidence of previous biliary disease.

TABLE 2.—*Abnormal Values in Liver Function Tests*

	Cause of Obstruction			
	Stones and Stenosis		Carcinoma	
Liver Function Test	No. of Cases	Percentage *	No. of Cases	Percentage *
Serum bilirubin	42	100	19	100
Alkaline phosphatase	28	66	16	84
Thymol flocculation	1	2	4	20
Cephalin flocculation	8	19	2	10
Total protein	2	6	1	5
Albumin	3	7	6	32
Globulin	13	31	8	42
Prothrombin time	2	6	3	15

* Percentage figures are approximate.

Of the 16 cases in this group which were jaundiced for a duration of 10 days to three months, 12 showed definitely low cholesterol ester values. There was no correlation with the absolute total cholesterol levels, some of which were low. The lowest ester value in this group was 25 per cent. Except for four cases in which the results of other liver function tests were abnormal, there were no other laboratory findings indicative of liver cell disease in the remaining cases. Of particular interest was one patient in whom jaundice developed after ligation of the common bile duct at the time of cholecystectomy. She had a very low ester percentage, with a high total cholesterol.

The alkaline phosphatase was high in most of the cases of this entire series. Protein fractionation was not considered a test specific for liver function.

Biopsies and autopsies in this group showed hyperplasia in the bile ducts, periportal fibrosis with lymphocytic infiltration and, in some of the cases, cloudy swelling and early degeneration of the liver cells. This pathology was found to be the same in practically all the

cases examined and was similar to the pathology of the liver in obstructive jaundice as described in the literature.[10]

Of the 19 cases of obstruction due to neoplasms a low cholesterol ester ratio appeared in 14 instances (70 per cent) (table 1). In the cases in which normal values were exhibited they were of short duration. Each case in which the jaundice persisted for more than eight days showed a significant drop in esters, some of them reaching extremely low levels. High total cholesterols were more frequent in this group than in the previous one, and a low total cholesterol value was not encountered here. Six patients in this group (32 per cent) showed an abnormally high total cholesterol. With the exception of the protein determination, in only four of these cases were the results of the other liver function tests abnormal, indicating hepatocellular damage.

The liver pathology in this group was essentially the same as in the previous series, with the addition of multiple metastatic lesions in many of them.

COMMENT

From the cases examined, it appears that the cholesterol esters may be significantly lowered in some cases of obstructive jaundice, which, with the exception of an elevated serum bilirubin and alkaline phosphatase, showed no or only few abnormalities in the liver function tests commonly used for the assessment of the hepatocellular function. The reduction of the cholesterol esters was noticed in the cases of obstruction due to calculi or benign stenosis, but was more pronounced in cases of obstruction due to neoplasms. The time factor was important in both groups, in that the reduction was commonest after the first week of jaundice.

The absolute values for the cholesterol esters obviously depended on the figures for total cholesterol. Although the ester percentage was lower in the group of malignant tumors, the total cholesterol values were higher than in the benign obstructions, and, therefore, the absolute values were, with one exception, higher than in the cases of obstruction due to benign processes.

Similar observations were made by Man and his coworkers,[11] who explained the relative and absolute diminution of esters on the basis of lack of excretion of free cholesterol in the bile.

As was stated before, the liver cell is the site of cholesterol esterification and release of the esters. It has been generally assumed, therefore, that the fall of cholesterol esters in biliary obstruction is a manifestation of secondary liver cell damage. The questions arise then, why in so many cases this is the first and only liver function test to give abnormal results, and why the results of the other tests commonly used should remain normal. Is the liver cell damage occurring in obstruction of a different type from the one encountered in hepatitis? Does damage resulting from biliary obstruction primarily affect the enzyme system necessary for cholesterol esterification?

Meyer, Popper, and Steigmann [6n] recently discussed the question of biliary hepatitis, that is, parenchymal damage due to extrahepatic biliary obstruction. These authors pointed out that infection is not necessarily a factor and confirmed the impression that increased pressure of the duct system seems to play a major role. The histological picture has been described as a "pure" biliary hepatitis differentiated from the purulent hepatitis. The mean figures given by the authors for cholesterol esters appear significantly lowered, although they do not permit a correlation with the values in other hepatic function tests in each case. Our findings concur with their observation that lower cholesterol ester values occur in malignant obstruction rather than in benign obstruction. Our results also agree with the statement by Ottenberg and Colp and Watson [12] that a low total cholesterol concentration is of particular value to one in ruling out obstruction of the biliary tract by tumor. Our own observations did not permit any correlation between the histological findings and cholesterol ester values.[13]

It becomes evident that in the differential diagnosis of jaundice the cholesterol ester value alone does not permit clinical differentiation between obstruction and primary liver cell damage. This has been stated by several investigators.[14] On the other hand, we may say that a case of jaundice which shows a low cholesterol ester ratio in the presence of normal values for other commonly used liver function tests is likelier to be due to extrahepatic biliary obstruction than to primary hepatitis.

Portis [1] expressed a similar view, and our own studies corroborate his observation. It also appears from our investigations that low cholesterol esters in obstructive jaundice may present a relatively early sign and do not necessarily occur in the later course of the disease. It may

again be pointed out though that a single test will not permit the evaluation of the pathological physiology of such a complex process as is encountered in a case of extrahepatic biliary obstruction.

SUMMARY

In a survey of 61 cases of obstructive jaundice proved by surgery or autopsy, the total cholesterol and the cholesterol ester ratio are evaluated. In cases of obstruction due to stone or benign stenosis, a reduction of the cholesterol esters was frequently observed in the absence of abnormal results in liver function tests commonly used for evaluation of hepatocellular damage. This was found to be commoner after the first week of obstruction. In obstruction due to malignancy, the relative cholesterol ester content showed an even greater reduction. We conclude, therefore, that the cholesterol ester ratio is of no significance in the differential diagnosis between obstructive and hepatocellular jaundice. On the other hand, a low cholesterol ester value in the presence of normal values in liver function tests suggests mechanical obstruction.

EVALUATION OF RADIOPHOSPHORUS THERAPY IN PRIMARY POLYCYTHEMIA

Charles F. Stroebel, M.D., Byron E. Hall, M.D.
and
Gertrude L. Pease, M.D., Rochester, Minn.

During the past decade, radiophosphorus has become a widely accepted agent for the treatment of primary polycythemia, and favorable experience with it has been reported by a number of investigators.[1]

In the eight year period from Jan. 1, 1942 through Dec. 31, 1949, 199 patients who had primary polycythemia have been treated with radiophosphorus at the Mayo Clinic. This group included 78 women and 121 men varying in age from 25 to 73 years, with a mean age of 54 years. The case records of this entire series were of value in the analysis of most pretreatment features. In the consideration of posttreatment features, inadequacy of treatment, failure to return, and recentness of treatment have reduced this total group to 148 patients.

In addition to the foregoing, we have considered a group of 32 patients with primary polycythemia who were treated with means other than radiophosphorus (phlebotomy, phenylhydrazine, and roentgen therapy), and the cause of whose death is known. In 10 patients of this group, necropsy had been performed at the clinic or elsewhere.

For the purpose of this study, the basic criteria of the primary polycythemic state are (1) a sustained elevation of the erythrocyte count at more than 6,000,000 cells per cubic millimeter of blood and (2) sustained elevation of the hematocrit or erythrocyte volume at more than 55% in the presence of a normal or increased total blood volume (Congo red method). In this fundamental set of criteria must be included anamnestic evidence that the polycythemia was sustained and not transient and objective evidence excluding known causes of secondary or relative polycythemia.

In addition to the foregoing basic criteria, there may be indications of myeloid hyperactivity as manifested by the presence of immature myeloid cells in the peripheral blood or hyperleukocytosis. In this study, the significant level of leukocytosis is set at 15,000 cells per cubic millimeter of blood.

Palpable splenomegaly may be present, and there may be hyperuricemia (uric acid levels of more than 6.0 mg. per 100 cc. of serum).

In this study, we have called special attention to cases in which the total blood volume was elevated. The upper limit of normal for this determination in our laboratories is 100 cc. per kilogram of body weight. To make this criterion unequivocal, we have chosen 110 cc. per kilogram as the lower figure for significant elevation of the total blood volume.

PRETREATMENT EVALUATION

The analysis of our data before treatment is considered under the following topics: (1) duration and subjective symptoms; (2) degree of elevation of the erythrocyte volume; (3) degree of myelopathy; (4) presence of hyperuricemia; (5) degree of splenomegaly; (6) incidence of vascular complications; (7) response to treatment other than radiophosphorus; (8) patterns in primary polycythemia.

From the Division of Medicine (Drs. Stroebel and Hall) and the Division of Clinical Laboratories (Dr. Pease), Mayo Clinic.

Duration and Subjective Symptoms.—The early symptoms of polycythemia may be very mild, and the onset insidious. Occasionally, however, in a patient under close observation the polycythemic state will develop acutely. For these reasons, statements of the duration of the disease are likely to be inaccurate and must be regarded as approximations.

In the series later treated with radiophosphorus, an estimate of duration was possible in 162 cases. Here the mean duration was 49.5 months. The range varied from "less than a year" to 20 years. The relation of duration and pattern of disease will be discussed later.

It must be emphasized that though relief of subjective symptoms is an important criterion in the judgment of therapy in primary polycythemia, inadequate therapy will often afford such striking relief of symptoms that change in the subjective character of the patient does not afford a reliable guide to therapy. In earlier papers, one of us (Hall)[2] has described the subjective symptoms of many of the group treated later with radiophosphorus and has pointed out the striking relief of symptoms in this method of treatment. In this present study, we have confined our observations to certain crucial objective findings.

Degree of Elevation of the Erythrocyte Volume.—As stated previously, this criterion is fundamental to the definition of primary polycythemia, and for purposes of definition we have arbitrarily selected hematocrit values of 55% or more as critical. Ninety-six (53%) of 182 cases in the radiophosphorus series exhibited total blood volume of more than 110 cc. per kilogram before treatment.

Degree of Myelopathy.—Leukemoid reactions (either the presence of immature leukocytes in the peripheral blood or more than 15,000 leukocytes per cubic millimeter of blood) were noted in 62 (32%) of 194 cases. Marked leukemoid reactions were noted in 10 cases (5%).

Presence of Hyperuricemia.—Elevation of the uric acid values to more than 6.0 mg. per 100 cc. of serum was noted in 46 (27%) of 169 cases in which this observation was made.

Degree of Splenomegaly.—The spleen was readily palpable in 130 (65%) of the total series of 199 cases.

Incidence of Vascular Complications.—In 62 (31.1%) of the total series of 199 cases there was a history of some sort of vascular accident prior to radiophosphorus therapy (hemorrhage 8.5%, thrombosis 19.6%, and both 3.0%).

Response to Treatment Other Than Radiophosphorus.—In 96 (48%) of the total series of 199 cases, some type of therapy other than radiophosphorus had been given prior to radiophosphorus treatment. In the majority of cases this had consisted of bleedings and phenylhydrazine. In a few cases roentgen therapy had been given over the long bones and the spleen. Four patients had received nitrogen mustard therapy with remissions of less than a year's duration. To our knowledge, none of the patients had been treated with "spray radiation." One patient was treated with bleeding and a low iron diet, but, in spite of this regimen, his polycythemia rapidly recurred.

In many instances, sufficient details of previous therapy were lacking, so that an accurate comparison with the later treatment with radiophosphorus was not possible. However, all patients accepted for treatment with radiophosphorus were in relapse, and with one or two exceptions, treatment that had been used before had not been notably successful in producing long remissions of a year or more (the criterion set up for judgment of the effect of radiophosphorus). In many cases, there had never been good objective control of the polycythemic state, but it should also be pointed out that patients receiving other forms of therapy were rarely, if ever, under the rigorous observation and control imposed on those receiving radiophosphorus. However, frequent bleeding and dietary restrictions impose a burden that few patients will accept over a long period of time. The difficulties in the use of phenylhydrazine are well known and need not be reviewed.

Patterns in Primary Polycythemia.—The foregoing incidences give only a piecemeal view of primary polycythemia. It is well known that certain factors are correlated in combinations to form certain patterns. First, there is the type largely characterized by the increased erythrocyte volume without striking evidence of other phases of myelopathy. Another well-known type is seen in the case with polycythemia plus evidence of other forms of myelopathy such as myeloid immaturity and thrombocytosis. In a third type the hematologic picture of either the first or second type described above occurs along with a history of vascular accidents.

The review of a series such as this, as is evident from the earlier paragraphs dealing with pretreatment data, shows that the first and second types represent relative extremes and are, in a sense, ideal. It is a debatable question where to draw the line of significant leukemoid reaction or leukocytosis in the peripheral blood. Nor can quantitative measure of the different fractions of the bone marrow give more than a relative answer. Neither is the significance of splenomegaly or hyperuricemia wholly appreciable in pretreatment analysis.

Often the original analysis of a given case is based on a single observation period. This may have followed a period of treatment with some other agent, which alters the picture considerably.

It is often assumed that "simple" polycythemia (that is, without evidence of panmyelopathy or complications) represents an early or mild form of a single disease and that if the disease continues long enough without a fatal vascular accident, increasing degrees of panmyelopathy will appear so that the terminal hematologic picture is either a myelocytic leukemia, an aplastic anemia, or a myelofibrosis with myeloid metaplasia.

The long history of the disease and the possibility of an easy form of treatment (bleeding) make attempts to know the natural course of the untreated disease or diseases virtually impossible. Nevertheless, an analysis of cases comparing incidence of leukemoid reaction with duration may be attempted for suggestive reasons.

In 143 cases of estimated duration of less than 10 years, 85 cases (59.5%) were of the "simple" type, and 58 cases (40.5%) exhibited a leukemoid reaction or leukocytosis. In 17 cases of estimated duration of more than 10 years, five cases (29.5%) were of the "simple" type, and 70.5% showed a leukemoid reaction or leukocytosis. It is apparent in this series that there is a higher percentage of cases of simple polycythemia in the group of shorter duration, while in the group of longer duration, there is a higher percentage of cases with leukemoid reactions. However, it is worthy of note that cases of "simple polycythemia" may be of considerable duration.

---

[2] Footnotes 1c through 1f.

One might infer from this that there is a tendency for older cases of polycythemia to become more myelopathic. However, the possibility must be considered that there is another fate for some cases of simple polycythemia. It is possible that some of these cases revert to normal, but we lack any documented record of this.

Another possibility is that the "simple polycythemias" may have a higher mortality rate in the earlier years from vascular accidents, although it would be difficult to see why this might be. In the pretreatment group of 62 cases in which there were histories of vascular accidents, in 31 cases (50%) there was no evidence of leukemoid reaction at the time of examination. In five cases, there were inconclusive data, and in the remaining 26 cases there were varying degrees of leukemoid reaction. From these data, it is thus impossible to associate vascular accidents with the presence or absence of panmyelopathy.

While these problems are of major importance in the characterization of primary polycythemia with no treatment or treatment other than radiophosphorus for comparison with primary polycythemia treated with radiophosphorus, they cannot be categorically settled at this time. For the present, it is a matter of being confronted with certain features sometimes grouped into combinations and noting what bearing they have on successful response to radiophosphorus therapy.

The combination of polycythemia, splenomegaly, and leukemoid reaction (immature cells in the peripheral blood) was noted in 48 of 194 cases (24.3%). Within this group there were 10 cases (5%) which showed very marked leukemoid reactions.

The combination of leukemoid reaction, splenomegaly, and hyperuricemia was seen in 17 cases out of 169 cases (10.1%). The combination of hyperuricemia and splenomegaly without leukemoid reaction was seen in eight cases (4.7%) out of 169.

Causes of Death in Primary Polycythemia Not Treated with Radiophosphorus.—For further comparison with the radiophosphorus series, study was made of the records of 32 patients who had had primary polycythemia, had received therapy other than radiophosphorus, and the cause of whose death was known. The methods of therapy employed consisted of bleeding alone, bleeding and phenylhydrazine, or roentgen therapy to the spleen and long bones. This group consisted of 19 men and 13 women with ages ranging from 30 to 74 years, the average age being 50.4 years.

In this group, the proportion of deaths from vascular accidents was very high, more than half (56.3%) of the group succumbing to thrombosis or hemorrhage. Leukemia accounted for 12.5% of the deaths (table 1).

While the group is not large, the distribution of the causes of death may be compared with duration of the disease from time of diagnosis. More than 80% (26 deaths) of the deaths in this group occurred within the first 10 years after diagnosis. During this first decade, the majority of the deaths (17) were from vascular accidents. The four cases of leukemia occurred in the second decade or later.

The study of a group of cases such as this emphasizes the high risk of vascular accidents in the case of primary polycythemia in which treatment is inadequate or absent. The appearance of leukemia in the second decade points out the necessity of a 20 year observation period before any definite conclusions about leukemia in polycythemia can be made, and the question of how many patients who might later have had leukemia died of vascular accidents early in the disease remains unsettled.

RESULTS OF TREATMENT WITH RADIOPHOSPHORUS

The method of radiophosphorus treatment[3] of primary polycythemia used at the Mayo Clinic consists of the following steps: (1) Venesections of 500 cc. each are repeatedly performed until the hematocrit has reached a level of 55% or less. In older persons or in persons who experience syncope with bleedings of 500 cc., lesser amounts are withdrawn, with a somewhat longer time interval between the bleedings. (2) When the hematocrit is at the desired level, radiophosphorus is administered. Radiosphosphorus is obtained as dibasic sodium phosphate in sterile isotonic saline solution. In the vast majority of instances, it is given intravenously. A very rare instance will require oral administration, in which case the dose must be increased approximately 30% to allow for failure of absorption. The initial dose given intravenously varies from 5 to 7 millicuries, depending on the therapist's judgment of the severity of the disease. (3) Thereafter, at intervals of six to eight weeks, the patient returns for blood examination at which time the hematocrit, hemoglobin, erythrocyte count, leukocyte count, platelet count, and morphologic study of a blood smear are done. (4) As long as the blood values are within normal limits (as defined previously) or low, no further radiophosphorus therapy is undertaken. When the polycythemic state recurs, the injection of radiophosphorus is repeated. A "course" consists of intravenous injections of radiophosphorus at intervals of six to eight weeks until a remission is obtained.

TABLE 1.—*Causes of Death of 32 Patients with Primary Polycythemia Treated with Means Other Than Radiophosphorus*

Cause of Death	No.	Percentage
Thrombosis		
Coronary	8	25.0
Mesenteric	3	9.4
Hepatic vein	1	3.1
Hemorrhage		
Cerebral	3	9.4
Gastrointestinal	3	9.4
Chronic myelocytic leukemia	4	12.5
Malignant tumors	4	12.5
Peritonitis	2	6.2
Others	4	12.5

---

[3] Stroebel, C. F., and Hall, B. E.: Radiophosphorus in the Treatment of Polycythemia Vera and the Leukemias, in Hahn, P. F.: A Manual of Artificial Radioisotope Therapy, New York, Academic Press, 1951.

In our experience, radiation sickness and local thrombophlebitis associated with the administration of radiophosphorus are virtually unknown.

The review of our series of 199 cases in which primary polycythemia was treated with radiophosphorus led to a rejection of 51 cases because of inadequate treatment, failure to give subsequent report, or therapy too recent to justify conclusions. Thus the evaluation of therapy is based on 148 cases.

The criteria used in the judgment of response to therapy are as follows: (1) Successfully treated: A complete remission of the polycythemic state developed after a course of radiophosphorus, and this remission lasted at least one year. The determination of "remission" is based entirely on objective data: the persistence of the erythrocyte count and hematocrit at normal or slightly subnormal levels. In this group, no striking abnormalities were noted in posttreatment leukocyte or thrombocyte counts or morphology.

(2) Successfully treated but hematologic complications developed: These patients had remissions from their polycythemia for at least a year, but a major hematologic abnormality other than recurrence of the polycythemia subsequently developed. The abnormalities noted consisted of anemia, leukemoid reaction, or even frank leukemia. Because of inadequate follow-up data in some instances, it is not always possible to state whether the anemia and leukemoid reaction seen represent myelocytic leukemia or myelofibrosis with myeloid metaplasia.

TABLE 2.—*Radiophosphorus Treatment of Primary Polycythemia: Distribution of Types of Response*

Type of Response	Patients	Percentage
Successfully treated	112	75.7
Successfully treated but hematologic complications developed	7	4.7
Failure	24	16.2
Failure with hematologic complication	5	3.4
	148	100.0

(3) Failure: In these patients, the amount of radiophosphorus given was comparable to or in excess of the amounts given in the first two groups, but these amounts were ineffective in producing remissions of at least a year. In this group, short remissions were often obtained, but it is particularly difficult in these cases to know if the remission was due to the bleeding program or to the radiophosphorus. If the criterion of success were based on a remission period of six months, the group of "failures" would be much smaller than that based on a remission period of one year. The selection of the period of a year or more was made, since in our experience remissions of this length are very uncommon when bleeding alone, bleeding and phenylhydrazine, or nitrogen mustard therapy is used. Many of the patients in the "failure" group obtained striking subjective remissions even though there was an early recurrence of polycythemia or only partial control achieved.

(4) Failures with hematologic complications: In this group there was no remission of the polycythemia lasting a year or more, and anemia, leukemoid reaction, or frank leukemia subsequently developed.

The observation period on 148 cases varied from one to eight years with a median observation period of 2.5 years. The mean observation period was 3.6 years.

The frequency of the type of response is indicated in table 2. In 80.4% of cases in which adequate amounts of radiophosphorus were given, a remission of the polycythemia state of at least one year's duration was obtained, and in many instances this was successfully repeated. This, however, includes seven cases (4.7% of 148 cases) in which anemia, leukemoid reactions, or frank leukemia developed. In 19.6% of the suitable cases studied, remissions of at least a year were not obtained; hence the cases are classified as "failures."

TABLE 3.—*Primary Polycythemia Successfully Treated with Radiophosphorus: Distribution of Pattern of Response*

Pattern of Response	Cases No.	Cases Percentage
Remissions with 7.0 mc. or less per course	47	42.0
Initial remission required more than 7.0 mc. but subsequent remissions induced with 7.0 mc. or less	16	14.3
Remissions required 7-15 mc.	38	33.9
Remissions required more than 15 mc.	11	9.8
	112	100.0

To obtain successful remissions, on the average, one or two intravenous injections yielding a dosage per course of 9 to 10 millicuries were required. The average remission obtained lasted well over one year (1.6 years).

Review of cases in which treatment was successful has shown that these usually fall into one of four groups of patterns of response to treatment, that is, a given patient will often respond in a similar manner with successive courses. In the first group (table 3) are patients who respond readily to relatively small amounts of radiophosphorus. In the second group, the initial remission may be obtained only after multiple injections, but once the remission has been obtained, successive remissions are obtained with relatively small doses of radiophosphorus. The last two groups are arbitrarily based on "moderate" requirements for remissions (7 to 15 millicuries per remission), and on "large" requirements for remissions (more than 15 millicuries per remission).

Durations of successful remissions lasted from one to two years in the majority of cases (50.4%). In 31.6% the remissions lasted two to four years. Duration of single remissions of more than four years was seen in 4.5%. In some cases in which remissions were otherwise successful, occasional remissions (13.5%) of less than one year were obtained.

TABLE 4.—*Hematologic Complications in Patients Who Received Radiophosphorus Therapy for Polycythemia*

Disease	No.	Percentage of 148 Patients
Acute leukemia	4	2.7
Chronic myelocytic leukemia	1	0.7
Anemia with leukemoid reactions	7	4.7
"Aplastic anemia"	1	0.7
	13	8.8

Major hematologic complications were seen in 13 patients as shown in table 4. The four patients who died of acute leukemia were all men, 49, 61, 63, and 67 years old, respectively. In these patients, the leukemia was a fulminating acute type without a preceding period of chronic myelocytic leukemia. None of the patients received more than 14.0 millicuries of radiophosphorus, and one of the patients had obtained a remission of one and a half years after a single injection of 7.0 millicuries.

Another patient was maintained in successful annual remissions for four years with doses of radiophosphorus varying between 4.9 and 7.0 millicuries per course. The other patients did not have successful remissions.

By no set of criteria could one predict that any one of these patients was potentially leukemic. In one patient there was a palpable spleen but neither leukemoid reaction nor hyperuricemia. Another had a palpable spleen, hyperuricemia, and high total blood volume but did not show a leukemoid reaction before treatment. The other two patients exhibited palpable spleens and leukemoid reactions.

The patient who died of chronic myelocytic leukemia was a man aged 51 years. At the time of first admission he exhibited pronounced splenomegaly and leukemoid reaction with high leukocytosis in addition to his polycythemia. He was under observation and treatment for six years, during which time he was given a total dosage of 76 millicuries in multiple injections, but he never obtained a satisfactory objective remission although he was somewhat improved symptomatically. His blood picture eventually became that of a chronic myelocytic leukemia with anemia.

Under "hematologic complications" we have listed the category "anemia with leukemoid reactions," since this best summarizes our knowledge of them. In only one of these patients has it been possible to do a bone marrow study, and in this case, multiple punctures have failed to yield marrow material suggestive of myelofibrosis and myeloid metaplasia. In this group of cases there were four women aged 48, 58, 68, and 71 years and three men aged 51, 63, and 67 years. Four of these patients had leukemoid reactions with their polycythemia before treatment, and three of these also had hyperuricemia. Another patient had splenomegaly and hyperuricemia but no leukemoid reaction before treatment. The remaining two patients had splenomegaly and elevation of the total blood volume but neither hyperuricemia nor leukemoid reaction. These patients have been under observation three to seven years. One patient was reported to have died of aplastic anemia, and another died of cerebral hemorrhage. The other five were still alive at the time of last report.

Hypoplastic anemia was noted in four patients after treatment. Only one of these patients needed transfusions because of the anemia. In this case, the anemia occurred after a single injection of 5.0 millicuries. The anemia lasted four months. Since that time, the polycythemia has recurred, and the patient has received further radiophosphorus therapy without event. In the other three patients, the anemia was mild and required no treatment. All these patients are included under the "successfully treated" group.

There have been 22 deaths in 148 cases. The contrast between the causes of death in table 5 and those of 32 patients not treated with radiophosphorus (table 1) is striking although the two groups are not altogether comparable, since the duration is generally greater for the group not treated with radiophosphorus. In the group not treated with radiophosphorus, the chronic leukemias tended to appear in the second decade, whereas all the deaths in the radiophosphorus-treated series have been actually observed only within the first decade.

The percentages of deaths due to vascular accidents are more comparable, as deaths from these tend to occur within the first decade. In the group treated by other means, 56.3% of the deaths were due to vascular accidents, whereas in the radiophosphorus-treated group, the incidence of death from vascular causes was 4.7%, less than one tenth of the incidence in the other group.

The review of vascular accidents in posttreatment cases shows, in addition to the seven patients who died, one patient who sustained a coronary thrombosis and is still alive. Five of these patients had had previous vascular accidents before treatment. In response to radiophosphorus therapy, only one had obtained a satisfactory remission. The other seven had failed to respond to treatment adequately.

It is worthy of note that two women in the radiophosphorus series were successfully treated for primary polycythemia and subsequently became pregnant. In both instances, no untoward events occurred during the pregnancies, and the infants born of these mothers were apparently normal. One patient, aged 25 years, had had symptoms of and treatment for polycythemia for nine years prior to examination and treatment with radiophosphorus at the clinic. She received two courses of radiophosphorus: one of 10 millicuries, the other of 6.4 millicuries. The pregnancy followed the last administration of radiophosphorus by several months, and the patient has continued in remission for more than two years. The other patient, aged 30 years, had had symptoms of six years' duration. She had splenomegaly, leukemoid reaction, hyperuricemia, and excessive total blood volume. Her condition was easily controlled on two separate occasions (two courses). A single injection of 5.7 millicuries was used in one course, a single injection of 4.9 millicuries in the other. The last remission has lasted more than two years, and it was in this remission that her pregnancy occurred.

TABLE 5.—*Causes of Death of 22 Patients with Primary Polycythemia Treated with Radiophosphorus*

Cause of Death	No.	Percentage of 148 Cases	
Acute leukemia	4	2.7	
Chronic myelocytic leukemia	1	0.7	
Aplastic anemia	1	0.7	
Congestive heart failure	2	1.4	
Coronary thrombosis	3	2.0	4.7
Cerebrovascular accidents	4	2.7	
Malignant tumors	3	2.0	
Pneumonia	1	0.7	
Postoperative hemorrhage	1	0.7	
Unknown	2	1.4	
	22	15.0	

COMPARISON OF PRETREATMENT DATA AND RESPONSE TO RADIOPHOSPHORUS

The analysis of pretreatment data given in table 6 and 6 A has been made to see if response to treatment could be predicted. It is evident from these tables that there is no absolute or exclusive criterion or combination of criteria on which success, degree of success, eventuality of hematologic complication, or failure may be absolutely predicted. However, certain tendencies are apparent.

First of all, among the four major categories of response (success, success with hematologic complications, failure, and failure with hematologic complications), there is a very high incidence of success (90.5%) in those cases of primary polycythemia in which only the basic criteria are present. Furthermore, in this group, no patients were seen with hematologic complications. In this group, devoid of what is usually considered to be indication of panmyelopathy, there were nearly 10% (9.5%) failures. The data suggest that the presence of the other criteria materially reduces the incidence of success, although the percentage of successful response is still high. Features such as splenomegaly, hypervolemia, history of vascular complications, and history of previous treatment do not seem to change the expectancy significantly from that of the entire series (75.7%).

When a leukemoid reaction is present, there is a somewhat lower incidence (65.9%), and when there is a marked leukemoid reaction, only 28.6% are treated successfully, although the number involved here was small, but it is noteworthy that even with this indication of pronounced myelopathy two patients have been successfully treated.

Those cases with hyperuricemia exhibited some further reduction in incidence of good result, as only 54.6% (18 patients) of the patients were successfully treated, 12% (four patients) had hematologic complications, and 33.3% (11 patients) had failures.

The group characterized by splenomegaly and leukemoid reaction had a lower incidence of success (58.2%) than that of all cases showing splenomegaly (72.8%) or all cases exhibiting leukemoid reaction (65.9%).

Successfully treated: More than 15 mc. per remission.........................	11	8	17.4	4	8.7	8	11.1	..	....	5	13.8	3	17.6	1	14.3
Successfully treated but hematologic complications	7	1	2.2	3	6.5	4	5.7	..	....	2	5.6	2	11.8	..	....
Failure	24	13	28.3	7	15.2	14	19.4	3	42.8	11	30.6	6	35.2	2	28.6
Failure plus hematologic complications	5	1	2.2	2	4.3	5	6.9	2	28.6	2	5.6	2	11.8	..	....
	148	46	100.0	46	100.0	72	100.0	7	100.0	36	100.0	17	100.0	7	100.0

When the group characterized by leukemoid reaction, splenomegaly, and hyperuricemia is considered, though the number considered is relatively small (17 cases), there seems to be a further reduction of incidence of success (41.2%).

Furthermore the incidence of hematologic complications seems to be greater in the group showing marked leukemoid reactions and hyperuricemia.

Cases of more than five years' duration show an incidence (67.3%) of successful results somewhat lower than those of the general series. The percentage of failure is higher, but the incidence of hematologic complications is not increased.

When only cases with successful response are studied and subdivided as to type of radiophosphorus course needed to induce remissions, we again note a relative tendency for the cases with basic criteria alone to require less radiophosphorus per course than others. Obversely, a higher proportion of those with leukemoid reactions, hyperuricemia and with the combinations of splenomegaly and leukemoid reaction, and of splenomegaly, leukemoid reaction, and hyperuricemia falls into the group that requires more radiophosphorus per course.

CONCLUSIONS

A study of 199 patients with primary polycythemia prior to radiophosphorus therapy reveals several "general" types: (1) a type characterized by increased erythrocyte volume in the presence of normal or increased total blood volume; (2) a type characterized by polycythemia plus evidence of panmyelopathy; (3) either the first or second type plus a history of vascular accidents.

The occurrence of vascular accidents shows no particular predilection for either the first or second type. Vascular accidents occurred in approximately one third of the cases before radiophosphorus treatment. The relation of leukemoid reaction to duration suggests that panmyelopathy is commoner with long duration.

A study of data on 32 patients with primary polycythemia treated with means other than radiophosphorus and the cause of whose death is known shows a very high incidence (56.3%) of death from vascular accidents, which tended to occur within the first decade. Leukemia accounted for 12.5% of the deaths, and these tended to occur later than the deaths from vascular accidents, although the incidence of leukemia occurring earlier may have been masked by the high mortality from vascular accidents.

Adequate posttreatment information was available on 148 of the original 199 patients. In the posttreatment group so far, there has been a decided reduction in the incidence of vascular accidents. Because of the factors mentioned previously, any comparison of the incidence of leukemia in the group treated with radiophosphorus and in groups treated with other methods is premature, since radiophosphorus has been used for a single decade or less. In the radiophosphorus-treated group, leukemia has occurred in approximately 3% of the group. Other hematologic complications bring the total for this type of event to 8%. In our opinion, this is a small risk compared with the much greater risk of vascular accidents (30% incidence in the pretreatment group as against 56.3% in the group in which the causes of death were known).

Radiophosphorus therapy is successful in producing remissions of more than one year's duration in three quarters of the cases. Simple polycythemia was successfully treated in 90% of the cases. The occurrence of leukemoid reactions or hyperuricemia in types manifesting some degree of panmyelopathy involved some reduction of the incidence of success.

UNITED NATIONS MEDICAL SERVICE IN KOREAN CONFLICT

Major General Edgar Erskine Hume,
Chief Medical Officer, United Nations Forces in Korea

In offering a preliminary report on the medical activities of the United Nations Forces in Korea, I have at once an unusual privilege and a difficult task, difficult because for reasons of security I cannot quote actual statistics and because conclusions about a campaign still in progress are necessarily incomplete.

The conflict in Korea is an unusual one in many respects. Never before have fighting men of so many nations and races joined together in a campaign within a single area of comparable size. Korea is about the size of Italy, and its mountains, though more numerous and more irregular in configuration, are strikingly like the Apennines. Veterans of the Italian campaign of 1944-1945 are struck by the similarity. Climatically Korea is difficult, for it is very hot and dusty in summer and bitterly cold in winter. The Korean climate is the coldest in which American soldiers have ever fought, and of course the troops from Thailand, the Philippines, and Ethiopia have never experienced anything like the subzero temperatures common in the Korean uplands in winter. In the spring there are heavy rains, turning the dirt roads into morasses, with consequent difficulties in transportation of the personnel and matériel of war. The time factor has been a major one in this campaign, for the conflict began without warning. With no advance notice it was necessary for the United Nations to send medical units into Korea to support the troops thrown in to resist the invading force from North Korea. This was done by depleting medical installations in Japan. Happily, this has since been corrected by the advent of additional medical units and personnel.

The conflict now raging in Korea is only a police action, not a war. Yet to those of us who must care for men wounded in this action, there is but little difference.

To give an idea of the magnitude of the military effort in Korea, I shall compare it numerically with the eight major wars which the United States has waged in its century and three-quarters of existence as a nation. Similar comparisons with the wars fought by the other United Nations could be made, had I the records available.

During the first eight months of the Korean campaign the United States Army has sustained nearly five times as many casualties as there were in the American Revolution (1775-1783), nearly 11 times as many as we had in the War of 1812, not quite four times those of the Mexican War (1846-1848), and over six times as many as in the Spanish-American War (1898). Only the War Between the States (1861-1865) and the two world wars have cost us more lives. The statistics used are those reported in private publications quoting the Department of Defense.[1] But it is not really possible to compare the casualties of one war with those of another on a categorical basis because of different classifications used. During the Revolution and War of 1812 the record did not differentiate between deaths in battle and those from disease. In later wars such separation was made, but it was not until World War II that the number of men who perished as a result of the enemy was greater than the number of men who died from disease. In the Mexican War seven men died of disease for every one killed by

---

Presented at the 13th International Congress of Military Medicine and Pharmacy, Paris, June 17, 1951.

[1] These data are based on unofficial statistics published weekly in *Time* magazine and in the "1950 Information Please Almanac." Both sources state that the material is from the Department of Defense, but the author is without official confirmation. No Korean conflict statistics as maintained in the Far East Command are used, these not being yet ready for release.

the enemy. And the War Between the States saw, on both sides, more than twice as many men mortally stricken by disease as were killed in battle or died of wounds. The brief war with Spain resulted in comparatively few battle losses, but more than 12 times that number died as disease victims. In World War I there were more deaths from disease, but the excess over battle deaths was not great. Then came our most costly war, World War II, wherein the age-old ratio was reversed and there were nearly 16 times as many deaths directly caused by the enemy as from disease. This great change was due not to increased lethal power of the enemy's weapons but to the magnificent strides made by military preventive medicine.

Let us consider some of the diseases which have through the ages been the most deadly killers of fighting men. Take, for instance, two which, though somewhat similar in name, are in no way related. One, typhoid, or enteric fever, is a warm-weather intestinal disease spread by contamination of food or drink. The other, typhus, is essentially a winter disease, transmitted in its epidemic form by the bite of an infected louse.

These two maladies have destroyed more soldiers in past wars than all the piercing or cutting weapons, firearms, and chemicals of armies in the field. No one charged with the duty of keeping the soldier fit to fight—which is the ultimate function of a military medical service—can properly perform his mission if he fails to recall what these two scourges have done to soldiers in the wars of which we have records.

Typhus, sometimes known as prison or jail fever, has accompanied man's misery from time immemorial, never more so than in war. We believe that Napoleon's failure in his invasion of Russia was due less to the "scorched earth" policy of the Russians than to the terrible outbreak of typhus. This fearfully fatal disease confers immunity on those who survive. And the Russians seem to have become protected against attacks of typhus by having earlier had that malady, perhaps in mild form. But the men of the Little Corporal's Grande Armée had not had typhus and fell victims to its ravages. The terrible winter retreat from Moscow followed, as every schoolboy knows. I have myself seen typhus at short range, first in the destructive epidemic in Serbia and other Balkan States during and after World War I, when dichlorodiphenyltrichloroethane (DDT) was unknown and we had to depend on steam sterilizers to destroy the infected lice. Secondly, I witnessed the epidemic in Naples in 1943-1944. By then we had DDT powder and with it disinfested masses of Neapolitan humanity to such effect that the epidemic was actually stopped and not one Allied soldier got the disease. So I have cause to fear typhus.

With these lessons in mind we have fought typhus in Korea and have managed to ward off epidemic incidence among United Nations personnel. But the enemy—and we know this from many sources, including statements made by prisoners-of-war—has not escaped. His troops have had epidemic typhus. One of our best medical authorities feels that, despite the appalling casualties inflicted by United Nations forces, there have been still more enemy fighting men destroyed or disabled by typhus.

The other major disease which has mowed down soldiers heretofore is typhoid. In past wars our soldiers have known it to their cost. Even though such misleading and meaningless terms as "typhomalaria," "bilious remittent fever," and the like have been used to hide the dreaded term "typhoid," yet prior to the end of the 19th century this malady alone was admittedly a more potent killer than enemy weapons.

America's first clear record of this disease in war was in our three-month campaign with Spain in 1898. The enemy killed few, indeed, of our troops. But "General Typhoid" struck them down with relentless efficiency. They died in camp, in transport, and in the field. It was at this juncture that Major Walter Reed and his co-workers showed how typhoid is transmitted from the sick to the well man, a splendid piece of scientific observation not to be confused with his yellow-fever studies. In the Spanish-American War thousands of our soldiers contracted this disease, and of the total number who died from disease, about one-half died of typhoid. In a few years there followed the immunization of our army against typhoid, and with that procedure we have reduced this disease to one no longer of prime military importance.

A few general statements will show what has happened to typhoid as a menace to our army. In World War I we had only 1,529 cases of this disease; but by standards of the Spanish-American War we should have had half a million. In World War II we had about 627 cases, but the expected number on the basis of the Spanish-American War rates would have been two million cases. And two million soldiers could turn the tide in even the largest war. But when we come to the conflict in Korea, where our men have had to live and fight in intimate contact with infectious material in rice paddies and in the soil on which their tents are pitched or in which their foxholes are dug, a greater danger from typhoid than ever arose. Yet we have not had half a dozen cases of typhoid fever among our troops in Korea. Probably never before in the history of wars has this been true. Strong words these, but true ones!

No better measure can be found as to the effectiveness of United Nations' preventive medical measures in Korea than to compare the epidemic and other disease conditions on our side with those on the enemy's side. We have found prisoners-of-war suffering from leprosy, tetanus (more than 200 cases), and other maladies which have been unknown among United Nations personnel. Smallpox in epidemic proportions has accounted for many enemy noneffectives and deaths, while with us constant watchfulness and hard work have saved United Nations forces from this menace. Intestinal parasites are so plentiful among prisoners-of-war in Korea that they are a factor in operative care of gunshot and other wounds of the alimentary tract. Among the general population or where protection against mosquitoes is inadequate, malarial incidence is very high. Yet chloroquine has been highly satisfactory (far more so than quinacrine [atabrine]) in its antimalarial protective and curative effects.

Certain maladies associated with the present war are being studied in special institutions and by special groups. Among such research units are those concerned with the treatment of burns, cold injuries, hepatitis, the dysentery group of diseases, malaria, and others. Such biological products as streptomycin, chloramphenicol (chloromycetin®), aureomycin, terramycin, corticotrophin (ACTH), and cortisone are among those being studied clinically. Neuropsychiatric patients are being considered in a somewhat new light.

One of the few good features of this campaign is the opportunity for medical research. Studies which in times of peace would require years may be completed in a matter of months, such being the tempo of the conflict. Much is quickly learned in clinical practice, also, in the fierce light of battle. All this is of great importance to youthful physicians drawn into the military service from peacetime professional pursuits of civil life. They have a wealth of clinical material and unrivaled opportunity to learn, and so when they return to their hospitals and other functions at home they will find themselves better qualified. This has been the subject of favorable comment by all the distinguished civilian consultants who come to Japan and Korea at the behest of the Surgeon General. One is reminded of the words of Hippocrates himself, "He who would become a surgeon should join the army and follow it."

It is hard to adjudge the effectiveness and efficiency of our military medicine and surgery other than by counting the number of fighting men who die in our hospitals. Obviously, wounded who perish before reaching a medical installation have never been patients and so are not included in medical statistics.

On the basis of the experience of World War II, we expected that 4.5% of all wounded who reached our military hospitals would die. But this calculation was incorrect. The death rate among battle casualities treated in our hospitals has actually been about half this. A proud figure indeed! In other words, thus far, of every 1,000 wounded men admitted to our hospitals 975 live. Municipal hospitals in large cities, those that care for the victims of ordinary accidents due to traffic, industry, and the like, can hardly match these figures.We hope that, with help of Providence, we can maintain this goodly record to the end of the conflict.

The problems incident to administering a medical service to soldiers, sailors, and airmen of more than a score of United Nations in Korea are exceedingly difficult. Methods and customs vary, racial susceptibility to disease is a factor. Diets, language, and religions are different. But all men of the United Nations forces are united in a common ideal, and have a will to fit into a composite force fighting for freedom of mankind. Few of the contingents from various countries have other than a small medical group for primary front-line medical care of their men. The number of their medical officers, nurses, and men is limited indeed. Consequently, the whole task of immunization, transportation, hospital care, supply, evacuation, etc., of all patients devolves largely upon the United States Army. Such care is extended to naval and air personnel as well.

One must see the smoothness with which this united medical service functions to believe it possible. We make no distinction in our hospitals as to the nationality, race, rank, or religion of our patients. They are separated solely on the basis of their clinical condition. Not once has there been any difficulty or complaint regarding this policy. No physician, civil or military, can be other than satisfied to see a general in the bed next to a private, a Frenchman beside a Filipino, or a Negro in a bed adjoining that of a man of some other race. We hold that nowhere is the spirit animating the United Nations more manifest. When requested, we provide special food for those whose dietary rules or national usage specifies a particular diet. And even this has caused us but small difficulty.

Never since the period of the Crusades have soldiers of so many nations been united in one great cause, and we may claim even more, for among the United Nations warring against a common foe we have descendants of races which in the Crusades of old fought on both sides. Our hospitals are places of good cheer, and men who have sealed their brotherhood by their very blood understand each other in a lasting way. We believe that the future strength of the United Nations will be the better for this.

The manner in which our blood bank functions is a splendid example of the good consequences of good cooperation. While we regularly receive the bulk of our blood stocks by airplane from the United States, all and sundry people in Tokyo and other Japanese centers contribute their blood generously. Donors come from every category of people, soldiers, sailors, and airmen whose duties do not take them to Korea, civilian women as well as men, and personnel of every diplomatic mission in Japan. Japanese people have given freely, coming from every walk of life from the brother of the Emperor to poor laborers. In a literal sense, our fighting men are united by ties of blood. The American Red Cross has effectively attended to much of the administrative detail in all this.

There have been many military medical advances growing out of our experience in Korea. We have found that the helicopter is a wondrous saver of lives. These aircraft are attached to Mobile Army Surgical Hospitals, our most forward hospital units, in which women nurses are on duty. Upon call from the aid stations in the area of actual combat, the helicopter is sent forthwith to bring back the wounded man. Thus, in a matter of minutes rather than hours the patient is brought into a hospital where he may receive operative care. I have repeatedly decorated men in a hospital within one hour from the moment they were wounded.

Other air evacuation methods have likewise been developed to a new high point of efficiency. Small airplanes transport patients to airfields where they can be placed upon larger craft. Agonizing rides over the terrible roads, cut to pieces by artillery and by heavy use, are thereby largely avoided, though there are tactical situations when no other transportation can be employed. We use large motor ambulances, accommodating a dozen or more patients. Some of these ambulances have auxiliary metal wheels which can be lowered so that the vehicle may run on railway tracks. We have splendidly equipped hospital trains with every modern facility that carry patients from point to point in Korea where such mode of travel is indicated. Our railway hospital cars have steel walls and bullet-proof glass, two necessary and practical features, for on many night journeys guerillas fire on the trains. Indeed, though we have not removed the Red Cross from our trains and ambulances, we have painted out the white background thereof. It too often served as a target, for the enemy does not respect the Red Cross and is not even a party to the Geneva Convention.

Never before has there been a war in which the wounded could be so speedily and effectively removed from the embattled country and taken to a land not at war. We do just that. The Air Force, and to a less extent the Navy, transport patients to Japan in a matter of a few hours. In the latter country we have facilities for separating them according to the nature of their wounds or maladies. Triage is effected en route.

There is not space, nor is it otherwise appropriate at this time, to describe the system in effect for supplying all our units with needed medical apparatus and stores. Nor can I include details as to our highly effective Dental Corps, whose officers not only render care to the patients' teeth but do splendid work in maxillofacial surgery. Our Veterinary Corps is charged with inspection and supervision of foods, not solely those of animal origin, as formerly. We have two women's corps. In addition to the Nurse Corps there is the Women's Specialist Corps, composed of dietitians, physical therapists, and occupational therapists. Besides these, members of the Women's Army Corps (WAC's), though not medically trained, are often assigned to aid our nurses in military hospitals, frequently as volunteers when their ordinary daily tasks have been finished. Some of the other United Nations have sent women to participate in this great united medical effort. Thus in our hospitals one sees nurses from France, the Philippines, Belgium, Greece, Thailand, Netherlands, Turkey, the British Commonwealth of Nations, and others working together. Language is no barrier. In our Swedish and Norwegian hospitals and aboard our Danish hospital ship, in our Indian field ambulance, and in our British Commonwealth installations, patients from each United Nation are received. And the system works beautifully.

We have many thousands of wounded and ill prisoners-of-war. In care of them we have scrupulously lived up to every word of the Geneva Convention. Swiss officers, representatives of the International Red Cross, have been most kind in their reports on our treatment of captured enemy personnel. They have told us that the enemy has refused them permission even to enter northern Korea, much less to visit prisoners-of-war. Enemy physicians and nurses serve beside those of the United Nations in our hospitals, an example of the ability of medical personnel to work together under every condition. A separate medical organization is charged with professional care of the many thousands of refugees who wander the roads and fill the cities of war-torn Korea. Medical service for these unfortunate men, women, and children forms no part of my present report.

The Korean conflict has been carried on for nine months as these lines are written. Obviously it is too soon to give statistics, nor would it be proper to do so while we are still fighting, for we must not divulge data that might help the enemy. Yet what I have written will give an idea of what has been and is being done.

When the campaign is over we can then report, in detail, the gallant conduct of our medical personnel under fire. Many have been killed; many, decorated for heroism. A story remains to be told that will make us all proud of our calling.

PANHYSTERECTOMY IN THE TREATMENT OF CARCINOMA OF THE UTERINE CERVIX

EVALUATION OF RESULTS

Richard T. F. Schmidt, M.D., Cincinnati

In every hospital increasing numbers of intraepidermal[1] and early[2] invasive carcinomas of the uterine cervix are being discovered through awakened popular interest and the various new diagnostic methods. Simultaneously the surgical treatment of carcinoma of the cervix is being reevaluated by Meigs, Morton and others. It is becoming apparent that surgical treatment of early cases may offer improvement in cure rates over irradiation therapy, but the extent of surgery required for a given case is debatable.

It has been suggested that ordinary panhysterectomy might be as effective as the more radical Wertheim operation with pelvic lymph node resection, on the theory that if the tumor is confined to the cervix it will be cured by panhysterectomy alone; if it has extended beyond the cervix, the radical operation will not effect a cure. The purpose of this paper is to determine, if possible, what results are obtained when patients with early carcinoma of the cervix are treated with ordinary panhysterectomy.

Unfortunately, the small numbers of early cases that have been recognized in the past have permitted little experience with this treatment. In 1943 Jones and Jones[3] reported 36 cases of early carcinoma of the cervix treated at the Kelly Clinic with panhysterectomy. All of these cases were clinical stage I with a malignant ulceration of less than 1 cm. in diameter (Schmitz I). They showed an absolute five-year cure rate of 41.6%. This did not compare favorably with the five-year cure rate of 57.5% for a wider group of League of Nations stage I lesions treated with irradiation at the same clinic. They concluded that panhysterectomy is not a satisfactory therapy for carcinoma of the cervix.

From the Department of Obstetrics and Gynecology, Western Reserve University and University Hospital of Cleveland.

[1] In this clinic the terms "intraepidermal carcinoma" and "carcinoma *in situ*" are used to include lesions which extend into gland spaces but have not broken through the basement membrane.

[2] "Early" is used throughout this paper to indicate slight or limited invasion rather than with reference to the duration of the lesion.

[3] Jones, H. W., and Jones, G. E. S.: Panhysterectomy Versus Irradiation of Early Cancer of the Uterine Cervix, J. A. M. A. **122:** 930 (July) 1943.

Sanders and Christensen[4] report that 17 patients with early stage I carcinoma of the cervix were treated with panhysterectomy alone at Henry Ford Hospital and a five-year cure rate of 82.2% was obtained, as compared with 66.6% in a somewhat similar group of 18 patients treated with irradiation alone.

TeLinde[5] believes that certain "extremely early" carcinomas can be treated successfully by wide panhysterectomy, consisting of generous excision of the parametrium and vagina, but without lymph node resection. In substantiating this he points out that Bonney,[6] employing radical panhysterectomy with lymph node resection, obtained a cure rate of only 5.5% higher than did Peham and Amreich[7] using only wide vaginal hysterectomy. Recently Galvin and TeLinde[8] have advocated wide panhysterectomy only for intraepidermal carcinomas, which they believe deserve a classification separate from stage I.

MATERIAL

The 36 patients presented here comprise two groups: One of 23 patients, treated between 1929 and 1944, for which five-year results have been investigated; and an additional group of 13 patients, treated between 1944 and 1947, for which three-year results have been gathered. These patients represent all who had a panhysterectomy with a concurrent diagnosis of carcinoma of the cervix during the time intervals covered. Adequate follow-up information was obtained for all patients. Of the 36 cases, there were 15 in which diagnosis of carcinoma was established prior to operation and surgery was the treatment of choice. In 18 cases carcinoma was not suspected; hysterectomy was performed for some other cause, and the diagnosis was made on pathological examination of the excised specimen. In three cases carcinoma was suspected but not confirmed prior to operation. The number of patients who received surgical treatment inadvertently is indicative of the incipient stage of most of the lesions in this series. It is reasonable to assume that such a group would offer the best available prognosis for surgical treatment.

Classification.—All the recognized lesions were classified as early stage I (League of Nations) prior to operation. Among the 18 patients without previous diagnoses, eight were found in whom no gross cervical lesion of any kind was seen. This was determined by a careful review of the physical examinations, operative notes, and pathological reports. In eight others a nonspecific lesion, usually described as an erosion, was present but did not excite in the examiner a suspicion of carcinoma. In two others there was gross carcinoma which should have been recognized clinically and these must be considered missed diagnoses.

It is interesting to note that the absence of a gross lesion did not necessarily indicate lack of invasion. Of the eight patients with no gross lesion, three showed definite invasion when examined microscopically and only the remaining five had intraepidermal invasion. This disparity between gross and microscopic appearances cannot be emphasized too often.

Type of Surgery.—With the following exceptions, all the operations were ordinary abdominal panhysterectomies: Two were vaginal hysterectomies in elderly women with prolapse; three were wide panhysterectomies with greater than average portions of parametrium and vagina excised. The latter, of course, were among those diagnosed prior to operation.

Cell Type.—Among the 36 cancers were four adenocarcinomas of the cervix, one of which was noninvasive. The remainder were squamous cell carcinomas which were classified as follows: six, well-differentiated; seven, partially differentiated; nine, poorly differentiated. An additional 10 lesions were classified as intraepidermal carcinomas.

Follow-up.—Adequate follow-up information was obtained for all patients in this series: for staff patients, from the gynecological tumor clinic of University Hospitals; for private patients, from their personal physicians who furnished the clinic with recent information, or sent their patients in for examination. For deceased patients the presence or absence of carcinoma and the cause of death were ascertained by postmortem examination, or by unequivocal clinical findings.

RESULTS

Table 1 shows results in the two groups: one followed from five to 14 years, the other followed from three to five years. The five-year group showed a cure rate of 65.2%, which might be the cause of considerable optimism until the more moderate rate of 53.8% in the three-year group is observed. It is interesting to note (table 2) that the three-year group contains a higher proportion of noninvasive lesions and that a markedly greater proportion of patients received adjunctive x-ray therapy, yet the cure rate is lower. There is no easy explanation of this apparent paradox except that the groups are small and chance distribution can alter the results significantly.

TABLE 1.—*Results in Early Stage I Carcinomas Treated with Panhysterectomy*

Follow-Up	Cases	Dead of Carcinoma	Living, with Recurrence	Living and Well	Cure Rate, %
Five year	23	8	0	15 *	65.2
Three year	13	4	2	7	53,8
Total	36	12	2	22	61,1

* Two of these patients died of heart disease, 9 and 11 years after operation, free of carcinoma.

TABLE 2.—*Results According to Microscopic Extension and Supplementary Irradiation*

	Cases	Panhysterectomy Alone	Panhysterectomy and Irradiation	Alive and Well	Cure Rate, %
Five year follow-up					
Intraepidermal	4	4 (4)*	0 (0)*	4	100.0
Confined to cervix	15	11 (8)	4 (2)	10	66.6
Extension beyond cervix	4	0 (0)	4 (1)	1	25.0
Total	23	15 (12)	8 (3)	15	65.2
Three year follow-up					
Intraepidermal	7	3 (3)	4 (2)†	5	71.1
Confined to cervix	4	0 (0)	4 (2)	2	50.0
Extension beyond cervix	2	0 (0)	2 (0)	0	0.0
Total	13	3 (3)	10 (4)	7	53.8

* Numbers in parentheses represent survivals in the group indicated.
† See "Comment" for explanation of these recurrences.

It is not expected that the three-year group will show a significantly lower cure rate when these patients have been followed for five years, for all of the recurrences in the five-year group appeared within three and one-half years following treatment. In fact, the average interval between treatment and recurrence was only 17 months. Probably a more accurate estimate of the five-year cure rate for the entire series would be about 60 per cent or slightly less.

Table 3 shows the results, previously reported by Dr. L. A. Pomeroy,[9] in 720 patients treated with radium and x-ray irradiation between 1919 and 1940. The results in all clinical stages are given to show the distribution.

COMMENT

Table 4 shows a comparison of five-year cures obtained at University Hospitals when early stage I carcinomas were treated with panhysterectomy (in some cases followed by irradiation) and by irradiation alone. Also shown are a similar series reported by Jones and Jones,[3] and the irradiation results from 24 hospitals in eight countries contained in the League of Nations report.[10] Although there appears to be a slight statistical advantage in favor of the panhysterectomy group, several considerations must be borne in mind: 1. The surgically-treated group contains significantly earlier cases since they were judged to be either early stage I or were so early that the patients were not thought to have carcinoma prior to operation. On the other hand, the cancers in the irradiated group were advanced sufficiently to be diagnosed clinically, and this group contained the full range of cases falling in the American College of Surgeons' clinical stage I. 2. When the present five-year group is enlarged to include the group in which three-year survivals are reported, a somewhat lower five-year cure rate will result. The maximum figure would be 61%; and it probably will be lower. This is no improvement over irradiation results obtained in this clinic.

Experience in this clinic, then, is consistent with that of Jones and Jones, although surgical results here are a little better. (Apparently the cases dealt with here were somewhat earlier, and none of the patients had to be assumed dead for lack of follow-up.) It seems doubtful that ordinary panhysterectomy is adequate treatment even for selected early carcinomas of the cervix. The wide panhysterectomy advocated by TeLinde might have produced a higher cure rate, but this is a matter of speculation.

Ordinary panhysterectomy may still have a role in the treatment of intraepidermal carcinoma. The obvious difficulty lies in establishing, prior to surgery, that a lesion is truly noninvasive. This difficulty is illustrated by two supposedly intraepidermal lesions in this series which were treated with surgery and recurred (table 2). Although both had been diagnosed as noninvasive by biopsy and by the original pathological examination of the excised specimens, when these sections were reviewed for the purpose of this study it was generally agreed that one of them was definitely invasive and the other was doubtful. If this error can be made when the entire uterus is available for examination, it is apparent that the problem is more acute with only biopsy material available prior to surgical treatment.

This is borne out by the fact that, in this series, biopsy prior to surgery was not a reliable indication of invasiveness as proved by survival. In 15 cases with biopsy prior to surgery which were studied, no better cure rate was obtained than among those with no preliminary biopsy.

TABLE 3.—*Results in 720 Patients Treated with Radium and X-Ray, 1919 to 1940*

	Cases	5-Year Cures	5-Year Cures, %
Stage I	44	28	63.6
Stage II	114	45	39.5
Stage III	451	104	23.1
Stage IV	111	2	1.8
Total	720	179	24.9

TABLE 4.—*Comparison of Five-Year Cures by Surgery and Irradiation*

	Cases	5-Year Cures	5-Year Cures, %
University Hospitals			
Panhysterectomy	23	15	65.2
Irradiation (L. A. Pomeroy)	44	28	63.6
Jones and Jones			
Panhysterectomy	36	15	41.6
Irradiation	87	50	57.5
League of Nations			
Irradiation (stage I only)	1,267	792	62.5

In conclusion, the findings in this clinic and those of Jones and Jones indicate that ordinary panhysterectomy is probably inadequate for early stage I carcinoma of the cervix. Although this operation should be effective for carcinoma *in situ,* every possible precaution should be taken prior to surgery to insure that the lesion is truly noninvasive. The wide panhysterectomy undoubtedly should be preferred for any early case if surgical treatment is to be undertaken.

SUMMARY

Thirty-six cases of early carcinoma of the uterine cervix treated with panhysterectomy, and in some cases with accompanying x-ray irradiation, have been presented. In 23 cases, observed postoperatively for five to 14 years, there was a five-year cure rate of 65.2%. In 13 cases followed from three to five years, 53.8% of the patients were alive and well at the end of the follow-up period.

These results do not compare favorably with those obtained by irradiation alone of a more advanced group of stage I carcinomas. The five-year cure rate by irradiation alone is 63.6%.

Ordinary panhesterectomy is probably not adequate treatment even for selected stage I carcinomas of the cervix. Wide panhysterectomy may offer better results.

200 Paramount Bldg. (6).

Hunger and Appetite.—Since these sensations are so frequently associated they tend to be confused in consciousness and it is often difficult to separate them clearly. The two are, however, essentially different, and appetite is not merely a less intense degree of hunger. The sensation of appetite may be experienced when the stomach contains plenty of food, and is therefore quite independent of hunger. On the other hand, though hunger is usually accompanied by keen appetite, this is not necessarily so. It is well known that the appetite may be lost though a feeling of emptiness and hunger be present. The two sensations also differ in that one (hunger) is unpleasant, while the other is pleasant.—Charles Herbert Best, M.D., and Norman Burke Taylor, M.D., *The Physiological Basis of Medical Practice,* Baltimore, The Williams & Wilkins Company, 1950, p. 604.

CLINICAL NOTES

NEONATAL RUPTURE OF THE STOMACH

Maurice Ross, M.D., Paul Stanley Hill Jr., M.D.
and
Carl M. Haas, M.D., Saco, Me.

Although rupture of the stomach in a newborn infant is rare, it is a condition in which early diagnosis and prompt treatment can be lifesaving. In 1943 Herbut[1] found 15 cases in the literature and reported the 16th case, the first in which a congenital defect of the musculature of the stomach wall was described and considered responsible for the perforation. Pendergrass and Booth,[2] in 1946, reported an infant 3 days old with two perforations of the stomach. One of the perforations was closed surgically, but the other, on the posterior wall of the stomach, was not found until autopsy, after the infant died on the fifth day of life as a result of a fibropurulent peritonitis. According to the authors, the appearance at autopsy suggested that the "latter perforation was present at the time of operation and was overlooked due to its position and the fact that when one perforation was found and closed, an inadequate search was made for another perforation." In 1947 Burnett and Halpert[3] reported perforation of the stomach in a 2 day old Negro infant with atresia of the pyloric portion of the stomach. The principal predisposing factor in this case was believed to be a congenital defect of the muscle coats of the stomach. This case was of particular interest in that there was no distal obstruction in any of the previous 17 recorded instances of perforation of the stomach, while there was no perforation in the two previously reported cases of obstruction. In January, 1950, Tudor[4] reported the case of a white boy, dying on the fifth day of life, in whom postmortem examination revealed a perforation through the upper end of the greater curvature of the stomach. There was no mention of any muscular defect. This brought the total number of reported instances of rupture of the stomach in newborn infants to 19.

This report concerns two more cases, one in which the patient died and the other in which he recovered with surgical treatment.

REPORT OF CASES

Case 1.—E. M., a white boy, was born on Feb. 17, 1950, after a normal pregnancy and uncomplicated delivery by low forceps following saddle block anesthesia. His mother was a 22-year-old primipara said to have Raynaud's disease. The birth weight was 6 lb. 9 oz. (2,975 gm.). Physical examination findings on Feb. 19, 1950, when he weighed 6 lb. 3 oz. (2,810 gm.), were entirely normal. His weight rose to 6 lb. 8 oz. (2,950 gm.) on Feb. 20, when he was eating 2 to 2½ fl. oz. (60 to 75 cc.) of an evaporated milk and dextri-maltose® formula every four hours and passing about four normal yellow pasty stools a day. At 2 a.m. on Feb. 21, 1950, he took about 2 fl. oz. of formula and appeared to be in good condition. About 5:30 a.m. on the same day the nurse noticed that he suddenly had become cyanotic and that his abdomen was distended severely. She tried to insert a tube in the baby's rectum but was unsuccessful. She placed the baby in a premature incubator to administer oxygen. Physical examination at about 6 a.m. revealed a cyanotic infant appearing to be at the very point of death, with shallow irregular respirations and an abdomen distended so that it was tight as a drum. Attempts to insert a soft rubber catheter into the stomach through the esophagus were unsuccessful. Neither gas nor fluid could be aspirated. An x ray of the chest and abdomen revealed a large amount of gas in the peritoneal cavity, with the diaphragm pushed up high. When a 20-gage needle was inserted into the abdomen just to the left of the umbilicus, large amounts of gas came out under increased pressure. Although respiration improved after this procedure, the infant's condition remained very poor, in spite of supportive therapy. He died at 3:30 p.m. on the same day.

An autopsy was performed one and one-half hours after death. When the abdomen was opened, a small amount of gas with a foul odor escaped. The abdominal cavity contained about 100 cc. of cloudy brownish fluid. There were large amounts of clotted fibrinous exudate on the surface of the abdominal organs, with most of the exudate in the left upper quadrant. At the upper end of the greater curvature of the stomach there was a large perforation, about 4 cm. long. The borders of this opening were irregular, frayed, and dark blue. Along the middle of the lesser curvature of the stomach was a firm area about 1 by 2 cm. with a reddish surface. No other gross defects were observed in the abdominal or thoracic viscera.

The stomach was removed entirely, placed in formaldehyde solution U. S. P. and sent to Dr. Joseph Porter, pathologist at the Maine General Hospital, Portland, Me. His report stated that he had received in formaldehyde solution a stomach measuring 6 cm. in length. It was a grayish-white color; in the fundus along the greater curvature was a circular defect which measured 3 by 1.5 cm., with well-rounded fairly smooth edges. When the stomach was opened, there was a small amount of greenish material. The mucosa appeared normal, and there was no evidence of hemorrhage in the mucosa. The pyloric ring was patent and did not seem to be thickened. Sections were taken through this opening in the stomach and through the pylorus and mucosa.

On study, the margin of this perforation of the stomach showed a moderate degree of congestion of many of the vessels and an inflammatory infiltrate, which had extended beneath the mucosa and submucosa and also downward to just above the muscular layer. There were also foci of hemorrhage in the submucosa. The mucous membrane in all sections showed a fairly pronounced congestion, with several small hemorrhages present in the mucosa and occasionally in the submucosa. The vessels at the margin of, and for a short distance into, the adjacent stomach wall were congested markedly, and an occasional one was thrombosed. There was no evidence of tumor. It was the pathologist's impression that this was an antemortem perforation of the stomach, with necrosis of the wall, possibly due to intramural hemorrhage.

Case 2.—W. B., a white boy, the first of twins, was born at 2:40 a.m. on May 6, 1950, weighing 6 lb. 6 oz. (2,890 gm.). His mother was 40 years old, and this was her fourth pregnancy. Her first two pregnancies had resulted in miscarriages and the third, on April 18, 1948, in a normal girl. This pregnancy had been uncomplicated, except for the fact that the mother suffered a great deal of discomfort during her last trimester, presumably because of the large size of the uterus. W. B. was somewhat sluggish immediately after delivery but breathed spontaneously and appeared to be doing well within 15 to 20 min. His twin sister, who was born 25 min. after he was delivered, weighed 6 lb. 9 oz. (2,980 gm.). Her neonatal period was complicated from May 11 to May 13 inclusive by intermittent twitching of her extremities, usually involving only one side at a time. Physical examination findings were normal after the twitching had subsided, and she has had an uneventful course since then. She was not given any treatment except for vitamin K.

Physical examination of W. B. on May 8, 1950, when he had already regained his birth weight, resulted in normal findings,

except for single transverse palmar creases. At 2 a.m. on May 9 he took 2½ fl. oz. of a formula of two-fifths evaporated milk and three-fifths boiled water, which he retained. At 5:30 a.m. he was observed to be cyanotic and to have a distended abdomen. About 10 min. later 3 to 4 cc. of a mixture of blood-stained mucus and material resembling coffeegrounds in appearance was aspirated from his oropharynx. He was given 4.8 mg. of menadione sodium bisulfite (hykinone®) intramuscularly, and x rays of his chest and abdomen were taken, both in the recumbent and in the standing positions. These revealed free air in the peritoneal cavity. A stomach gas bubble could not be discerned. Although this infant presented a picture similar to that seen in case 1, his condition did not appear to be as critical as the patient's in that case.

With the patient under drop ether anesthesia with oxygen at 7:30 a.m., the abdomen was opened through a right rectus incision. Air escaped under pressure when the peritoneum was opened, and there was some fluid in the cavity. On the greater curvature of the fundus of the stomach was an elliptical defect about 4 cm. long in the musculature of the stomach wall. The defect had V-shaped ends, as if the muscle layers had pulled away from the greater curvature. The only part of the stomach wall that seemed to remain in this defect was the mucosa, through which it seemed as if dark stomach contents were visible. This defect was closed by suturing together the edges of the muscle bundles. About 2 cm. above the pylorus, on the anterior surface of the stomach, a perforation about 1 cm. in diameter was found and closed. A catheter was inserted into the stomach through the nose before the stomach was closed. The patient stood the surgical procedure well.

Postoperatively he was given transfusions twice daily of citrated whole blood until he had a total of seven transfusions. Treatment also included oxygen and the administration parenterally of penicillin, sodium sulfadiazine, adrenal cortex extract, vitamin B and C, isotonic sodium chloride solution, 5% dextrose in water, and protein hydrolysate. On the day of operation his rectal temperature rose to 103.2 F., but it declined steadily until May 12, 1950, when it became normal and remained so. The patient was not fed anything by mouth until 8:30 p.m. on May 11, when small feedings of 5% dextrose in water were started every two hours. Two days later his feedings were changed to a dilute mixture of dryco® and dextri-maltose® in water, which was gradually increased in strength. The catheter which had been inserted in his stomach through his nose was removed on May 14, when he was started on oral administration of a multivitamin preparation. On May 28 a small superficial stitch abscess developed, which cleared up in three days with treatment with isotonic sodium chloride solution soaks. On June 1, when he weighed 6 lb. 13 oz. (3,100 gm.), his formula was changed to equal parts of evaporated milk and water, of which he took 3 fl. oz. (90 cc.) every three hours. Weighing 6 lb. 15 oz. (3,150 gm.) and in good condition, the patient was discharged home on June 5, 1950. When seen on June 16, 1950, he weighed 8 lb. (3,630 gm.) and was doing well. When examined on March 3, 1951, he was in excellent health.

SUMMARY

Two cases of rupture of the stomach in newborn infants, occurring approximately 85 and 75 hr. after birth, are reported. The second case is of special interest because the patient had a congenital defect in the musculature of his stomach and, as a careful search of the literature has not revealed any reports of survival from this condition, is believed to be the first one reported to have survived rupture of the stomach in the neonatal period.

ADDENDUM

Since this paper was submitted for publication, Wright and Scott[5] reported a case of perforated gastric ulcer in a newborn infant who died on the sixth day of life before operation could be performed.

372 Main St. (Dr. Ross).

ANAPHYLACTIC REACTIONS FROM LOCAL USE OF PENICILLIN

REPORT OF TWO CASES

Reginald Everett, M.D., New York

Four reports of anaphylactic reactions from penicillin have been found in the literature, in all of which the reactions were secondary to intramuscular injections.[1] The following cases are of interest because up to the time of writing there had been no report of similar reactions due to the local use or topical application of penicillin.

REPORT OF CASES

Case 1.—A white man, aged 57 years, in good general health except for moderate hypertension and recurring upper respiratory tract infections, was treated on Nov. 26, 1949 for subacute left maxillary sinusitis. The left antrum was irrigated through the natural ostium, and 1 cc. of mucopus was returned. The saline solution was displaced by air, and 30,000 units of crystalline penicillin G and 9.9 mg. of l-ephedrine in 4 cc. of 2.5 per cent "sulfisoxazole" (gantrisin®—3,4-dimethyl-5-sulfanilamido isoxazole) were instilled into the antrum. The patient had an almost immediate flushing of the face, choking, wheezing, dyspnea, and extreme circulatory depression with rapid, weak, almost imperceptible pulse, and profuse perspiration. This occurred with great suddenness while he was in the treatment chair, and before he could be got into the horizontal position, he lost consciousness. The reaction was one of immediate and alarming shock.

The patient was known to have hypertension, and as ephedrine had already been instilled into the sinus, epinephrine was not given. At the first onset of flushing of the face, 25 mg. of diphenhydramine hydrochloride and 100 mg. of aminophylline were given by mouth. When the circulation became so depressed, 0.5 gm. of caffeine and sodium benzoate was given hypodermically.

At the time a penicillin reaction had not been suspected because the patient had been entirely free from reactions when penicillin had been previously administered, which was as recently as five weeks. Up until this time, with considerable use of penicillin instilled locally into the sinuses, I[2] had had no patient with immediate penicillin reactions nor to my knowledge had any such reactions been reported in the literature.

The patient regained consciousness soon after being placed in a horizontal position. However, his general condition improved so slowly that it was about three hours before he recovered sufficiently to be removed to his home. There was no urticaria or skin rash. The next day, aside from being weak, he felt fairly normal.

The previous history had not indicated fungus infections, and the only discernible allergy suggested by the history was the presence on a few occasions of considerable sneezing and mucous discharge following treatment by a rhinologist. This was before the general use of penicillin, which therefore could not have been a factor.

Three months later, having received no treatment in the interim, while in another city on business and having an acute upper respiratory tract infection with about a 1 degree elevation of temperature, he called upon a physician and requested a "shot of penicillin." Receiving assurance from the patient that he had had no previous reactions from penicillin, the physician gave him 300,000 units of crystalline penicillin G procaine in peanut oil with 2 per cent aluminum monostearate, and, in the words of the physician, "within 15 minutes he had one of the severest manifestations of shock I have ever seen."[3] His blood pressure was 190/110 before the injection but immediately thereafter dropped to 90/60, the pulse became thready, and he broke out in a dripping perspiration. There was no precordial or radiating pain. He was put to bed in the office with warm blankets and external heat. Fifteen minims (1 cc.) of epinephrine hydrochloride was given very slowly hypodermically, and his blood pressure gradually rose to 150/90. Soon his condition improved, and after two hours in bed he felt quite normal again. There was no urticaria or skin lesions. The patient described the reaction as similar to the one in my office some months ago.

[3] Kaufman, H. M.: Personal communication to the author.

That sensitivity to penicillin had been induced in this patient, there can be no doubt. A review of his record shows his first contact with penicillin to have been in Feb., 1945, when 2,500 units of plain penicillin was instilled into the antrum. From then until November, 1949, he received 16 separate instillations of penicillin into the sinuses in doses ranging from 2,500 units to 40,000 units. In 1947 he received four intramuscular injections of plain penicillin of 100,000 units each, in 1948 two 300,000 unit injections of penicillin in oil and wax according to the Romanski formula and five injections of 300,000 units of crystalline penicillin G. All were entirely free from any side reactions or allergic manifestations. Only five weeks previous to his first reaction, 30,000 units of penicillin had been instilled into the antrum with no ill effects of any kind.

CASE 2.—A white man, 50 years of age, had emphysema and a chronic left maxillary sinusitis which became acute recurrently with each attack of coryza. Antrotomy had repeatedly been advised, but the patient steadfastly refused operation.

He was known to have asthma when in contact with horses and could not eat hard shell clams because of severe and immediate gastric symptoms. Once after oral ingestion of penicillin he had slight itching of the skin, which promptly disappeared after taking one or two 50 mg. tablets of tripelennamine hydrochloride. There was no history of any fungous infection.

On Feb. 8, 1950, because of a recent flare-up of the sinusitis, the sinus was irrigated, and 1 fluidrachm (4 cc.) of pus was returned. Thirty thousand units of penicillin and 9.9 mg. of l-ephedrine in 4 cc. of sterile water was instilled into the antrum through the natural ostium. Within a few seconds his entire skin became red and edematous, with intense itching, and severe asthma appeared. Fifty milligrams of tripelennamine hydrochloride was given by mouth and 0.5 cc. of epinephrine hydrochloride hypodermically which resulted in prompt relief. He was placed on a couch in the office, and after an hour all symptoms had disappeared and he felt quite normal. This patient had received frequent instillations of penicillin into the sinus from October, 1948, to February, 1950; he had also received over 3,000,000 units of crystalline penicillin procaine intramuscularly from November, 1947, to December, 1949, without any ill effects. Subsequent history, however, revealed that during the last three weeks of January he had used aerosol penicillin for the emphysema and at the end itching of the skin developed, which was promptly relieved by a few 50 mg. tablets of tripelennamine hydrochloride.

COMMENT

Long[4] has cautioned that repeated courses of penicillin therapy increase the possibility of producing an allergic state, especially its topical use on mucous membranes and abraided or weeping surfaces. It would appear likely that with the continued, extensive use of penicillin the number of cases of sensitivity will increase, and that in patients now receiving penicillin with no apparent side effects sudden and unexpected anaphylactic reactions may develop.

SUMMARY

Two cases of anaphylactic reactions from instillation of penicillin into the maxillary sinuses are reported and are probably the first due to local application. Both patients over a period of years had received penicillin therapy without ill effects and were probably sensitized by repeated exposure.

DIAPHRAGMATIC FLUTTER WITH SYMPTOMS RESEMBLING ANGINA PECTORIS

Wallis L. Craddock, M.D., Jefferson Barracks, Mo.

One of the most fascinating medical cases concerns that of paroxysmal flutter of the diaphragm. From time to time accounts of the rare condition come to the attention of physicians who have observed an irascible individual who has made a livelihood of exhibiting his affliction in various institutions. The patient, Walter E. Urwiler, is 69 yr. of age, and, although he enlisted in the Army on two occasions, he is not entitled to care by the Veterans Administration because of desertion in both enlistments. Since 1935 six reports concerning his case have been published in medical journals. Recently, Federal charges against him were dismissed, and he was ordered released to the Army for disposition as a deserter.

In all instances of reported hospitalizations there have been evidences of psychopathy, malingering, belligerency, and procacity. Aliases are numerous and include the following: John J. Allen, Lewis Allen, Charles Blackwell, Charles Bennett, Frank Crawley, Timothy Dawson, George Drye, Joseph Mixen, James Rinhart, Robert Romford, Robert Keaton, and Joseph Zelly. His "occupations" have been given variously as prospector, trapper, hard-rock miner, deep-sea diver, bandit chaser and Texas sheriff, wealthy sheepman, and an officer in both the Army and the Navy. During more recent hospital tenures he has entertained fellow patients with his exploits as a drummer boy during the American Civil War and as a prisoner of the Japanese at Santo Tomas. He asserts that as a Regular Army officer he participated in assaults on Tarawa, Saipan, Iwo Jima, and Okinawa. He stated that the scars on his neck represented "stab wounds" inflicted during the Tarawa invasion. On another occasion he asserted that the scars were due to old operations for tuberculosis.

It is likely that the patient is now being treated at some hospital for symptoms resembling coronary occlusion, demanding narcotics and oxygen, and entertaining all with his many exploits. Accounts of his many stories and fabrications would be endless. It is the purpose of this report to give a summary of the case to date, commenting on the aspects of the diaphragmatic flutter.

From the Medical Service, Veterans Administration Hospital, Fort Logan, Colorado, and Medical Center, University of Colorado School of Medicine. Sponsored by the Veterans Administration and published with the approval of the Chief Medical Director. The statements and conclusions published by the author are a result of his own study and do not necessarily reflect the opinion or policy of the Veterans Administration.

REPORT OF A CASE

Hospitalizations which have been listed in various reports are as follows: Colorado General Hospital, Denver, May, 1936; University of California Hospital, Berkeley, Calif., January 1937; Ventura County Hospital, Ventura, Calif., March, 1937; Oakland Regional Station Hospital, Oakland, Calif., September, 1944; Weimar Joint Sanitarium, Weimar, Calif., 1942; Dibble General Hospital, Calif., 1943; Veterans Administration Hospital, Livermore, Calif., 1943; Highlands-Alameda County Hospital, Oakland, Calif., 1944; Palo Alto Hospital, Palo Alto, Calif., August, 1946; Veterans Administration Hospital, Chamblee, Ga., June, 1948; Veterans Administration Hospital, Ft. Logan, Colo., November, 1948; Veterans Administration Hospital, Fayetteville, N. C., February, 1949; Fitzsimons General Hospital, Denver, December, 1949; Veterans Administration Hospital, Ft. Bayard, N. M., December, 1949; Veterans Administration Hospital, Tucson, Ariz., December, 1949; Veterans Administration Hospital, Houston, Tex., December, 1949; Veterans Administration Hospital, Columbia, S. C., January, 1950; Naval Hospital, Portsmouth, Va., February, 1950.

The patient is an asthenic white man, identified by his white hair, marked nasal septal deviation with occlusion of the right nostril, and two healed depressed scars on each side of the neck, which measure 5 cm. in length. He usually wears a beard, and reliable reports give his age as 69, his height as 5 ft. 6 in., and his weight as 100 to 110 lb. (45.4 to 49.9 kg.). There is a tattooed wreath of flowers on the left arm, just above the wrist, and a tattooed American eagle on the right arm. Adequate photographs are available from the FBI.

The hospital admission usually is attended with various theatricals, the patient pounding the left side of the chest with his fist and complaining bitterly of "pain in my heart." Despite irregular breathing with periods of apnea, there has been no evidence of circulatory impairment or cyanosis. A loud "tick-tock" sound of unequal intensity is heard throughout the chest. The ratio of this sound to the heart beat is about 3: 1 or 4: 1. If one can concentrate during the examination of the patient, despite the loud moans and cries, one can detect a regular heart rate of 60 to 66. The mean blood pressure is 110/70. In almost every instance the cardiac mechanism has been reported normal, with absence of murmurs, thrills, shocks, or unusual electrocardiographic changes. Routine laboratory findings, including complete blood counts, urinalysis, serology, and erythrocytic sedimentation rate, have been normal. Cardiac fluoroscopy has been done during many hospitalizations, revealing the markedly rapid rhythmic fluttering movement of the diaphragm, synchronous with the very audible "tick-tocks." The cardiac silhouette is normal. The studies of Goodman[1] were amplified by simultaneous electrocardiogram and phonocardiographic records. He was able to stop the flutter promptly by chilling the skin overlying the right phrenic nerve with ethyl chloride spray, suggesting the use of such a maneuver for "temporary control of this cardiodiaphragmatic syndrome and possible intractable hiccup."

It is common for the patient to be on the critical list. Unless physicians are aware of the details of the case, administration of opiates, oxygen, and various stimulants will continue. His numerous hospitalizations have already cost taxpayers thousands of dollars.

Attempts to control the diaphragmatic flutter have included left phrenicotomy, bilateral phrenic-nerve injections with procaine hydrochloride and alcohol, carbon dioxide-oxygen inhalations, and bilateral phrenemphraxis. Only temporary "relief" has ever been afforded, and a feigned "hemiplegia" followed one of the procedures. Despite close observation during one hospitalization, Whitehead and others[2] were puzzled by the detection of transient hyperpyrexia, with temperature elevations of 109 F. and 112 F., checked by rectum, mouth, and axilla, being recorded.

COMMENT

Porter[3] concluded that this case could be classed as a definite clinical picture (cardiodiaphragmatic syndrome) directly related to a functional disturbance of the diaphragm, and he suggested that abnormalities of diaphragmatic motility are more frequent than has been realized, the symptoms being mistaken for those of coronary thrombosis. Cain and Ware,[4] as well as Senter and others,[5] stressed this fact.

During both the acute and chronic stages of epidemic encephalitis, disturbances of diaphragmatic motility have been reported and classified by Marie[6] as to (1) abnormalities of the respiration proper, such as tachypnea and bradypnea, (2) spasmodic cough, and (3) respiratory tics, Dowman[7] and Gamble and others[8] have recorded cases of postencephalitic diaphragmatic tic which were more or less permanently relieved by interrupting the phrenic nerve by injections of procaine or alcohol or by sectioning, crushing, or removing the nerve.

Strauss[9] studied the distribution of phrenic nerves to the diaphragm in numerous animals and in man. He found a great deal of similarity in distribution in different species and concluded that fibers from one phrenic nerve were never observed to supply the opposite half of the diaphragm. The intercostal nerves were never found to supply the diaphragm in any of the mammals studied.

Moore and Schoff,[10] agreeing with the views of other clinicians, feel that an accessory phrenic-nerve supply exists in the patient and also add that the possibility of a "myotonic tic" of the diaphragm or lower intercostals may produce the disturbance. A post-mortem study in this case might add considerable light to the problem.

SUMMARY

A transient elderly male prevaricator has been admitted periodically to hospitals in various parts of the country. He seeks relief from "attacks" of acute precordial pain. It is not believed that paroxysmal flutter of the diaphragm, the very interesting phenomenon exhibited by the patient, is the cause of pain. However, certain clinical features of the case continue to remain a puzzle, including the etiology of the bizarre behavior of the diaphragm and the episodes of transient hyperthermia. A summary of the case has been given with a discussion of certain etiological factors which should be considered. The medical itinerary of the patient is not yet complete, and warning is made for the purpose of recognizing the patient during future hospitalizations.

SYSTEMIC BLASTOMYCOSIS TREATED WITH STILBAMIDINE

A PRELIMINARY REPORT

Emanuel B. Schoenbach, M.D.
Joseph M. Miller, M.D.
Milton Ginsberg, M.D.
and
Perrin H. Long, M.D., Baltimore

Generalized North American blastomycosis is generally a fatal disease. Iodine or x-ray therapy may cause a temporary recession of the lesion. In 1945 Elson [1] reported that certain of the diamidines exerted a fungistatic effect on Blastomyces dermatitidis in vitro. This observation had been noted and discussed by one of us [2] in a review on the pharmacology, mode of action, and therapeutic possibilities of the aromatic diamidines. When the patient suffering from systemic blastomycosis, whose case history will subsequently be described, was admitted to the Veterans Administration Hospital at Ft. Howard, Md., it was deemed advisable to treat him with two of the diamidines.

REPORT OF A CASE

A 33-yr.-old Indian was admitted to another hospital on July 15, 1950. He complained of difficulty in swallowing for about one year. Dysphagia had been so severe during the previous five months that he had lost about 40 lb. (18.1 kg.) in weight. The roentgenogram of the esophagus, made on July 23, showed after the administration of barium a marked narrowing of the lumen for 3 cm. at about the level of the second and third thoracic vertebrae. Esophagoscopy performed on July 28 revealed a firm, nodular, annular, constricting, and grossly malignant-appearing lesion at the junction of the upper and middle thirds of the esophagus. Biopsy did not show any neoplastic cells. Mirror laryngoscopy findings on Aug. 3 were reported normal. Esophagoscopy was repeated on Aug. 5, and again biopsy from the esophagus did not demonstrate neoplastic changes. Attempts to pass a Levin tube at this time were not successful, but a small esophageal bougie was introduced through this area of stenosis. That night the patient complained of severe pain just to the left of the sternum, at the level of the fifth to the seventh ribs. Crepitation was noted in the subcutaneous tissues over the left clavicle. The roentgenogram of the chest showed a mediastinal collection of air. The mediastinitis responded slowly to conservative treatment. A gastrostomy was performed on Aug. 15 because the patient could not swallow food. Fluoroscopy and roentgenograms made after swallowing iodized oil (lipiodol®) on Aug. 25 showed a fistula extending from the esophagus into the mediastinum. Iodized oil was also seen in the trachea, the right main bronchus and its larger subdivisions, indicating the presence of an esophagotracheal fistula. A mediastinal abscess was also demonstrated by these examinations.

On Aug. 28 a portion of the left ninth rib was resected, and an effusion in the posterior mediastinum, as well as an anterior mediastinal abscess containing 200 cc. of purulent matter, were drained. Aerobic and anaerobic cultures made from material in the posterior mediastinal collection were sterile. The same results were reported from material in the anterior mediastinal collection of purulent matter, except that one culture showed a "yeast" which was reported as a probable contaminant. The patient did well postoperatively. Mirror laryngoscopy on Oct. 4 showed that the right side of the epiglottis, the right side of the larynx, and both vocal cords were red and edematous. Although the presence of a carcinoma had never been proved, the patient was transferred to another hospital with the diagnoses of annular carcinoma of the esophagus, esophagotracheal fistula, and bronchopleurocutaneous fistula.

At the second hospital the diagnosis of carcinoma of the esophagus was not confirmed, and it was recommended that the patient be sent to a center for thoracic surgery in the Veterans Administration.

The patient was admitted to the Veterans Administration Hospital, Ft. Howard, Md., on Nov. 8, 1950. His condition was unchanged from that described above. The epiglottis was thick and covered with a granular, friable lesion. The disease extended to the posterior pharyngeal wall and into both pyriform sinuses. A mucosal erosion was seen in the left main bronchus about 2.5 cm. below the carina. The upper portion of the esophagus was red and roughened, and an obstruction was encountered about 2.5 cm. below the cervical constriction. Biopsy from the epiglottis showed that the infection was due to B. dermatitidis. Three hundred thousand units of aqueous crystalline procaine penicillin G were given intramuscularly daily from Nov. 25 through Dec. 13. An abscess in the lower portion of the anterior cervical region was incised and drained. B. dermatitidis was isolated on culture from the purulent drainage material.

The patient was placed on a low protein, low purine diet on Dec. 15, since this type of diet is reported to favor the action of stilbamidine (4,4'-stilbenedicarboxamidine). Treatment with stilbamidine and propamidine (4,4'-diamidino 1,3-diphenoxy propane) was started on Dec. 16. Since fibrin and desoxyribonucleoprotein are important components of inflammatory exudate, it seemed well to remove them from the involved areas by using streptokinase and streptodornase. Twenty-five thousand units of streptokinase and 15,000 units of streptodornase dissolved in 5 cc. of isotonic sodium chloride solution were inserted into the left bronchopleurocutaneous fistual. After an incubation period of four hours the wound was washed with 3 cc. of isotonic sodium chloride solution, and 5 cc. of a 0.1% solution of propamidine in 5% dextrose in distilled water was inserted into the fistula. The nasopharynx was sprayed with a sodium chloride solution of the enzymes, and after four hours the solution of propamidine was sprayed into the nasopharynx. Stilbamidine (0.05 gm.) in 100 cc. of 5% dextrose in distilled water was given slowly intravenously.

On Dec. 18 the intravenous dose of stilbamidine was increased to 0.1 gm. All other treatment as outlined above, was continued. In addition, the topical application of 25,000 units of streptokinase and 15,000 units of streptodornase to the wound in the neck was employed. The amount of stilbamidine was increased to 0.15 gm. on Dec. 20. By Dec. 22 the wound in the neck was unusually clean, but it was slow in healing. Daily treatment with 0.15 gm. of stilbamidine given intravenously was begun on Dec. 22 and continued through Jan. 3, 1951. Marked improvement in the patient's general condition occurred. A gradual decline in the febrile course was noted, and the temperature reached normal limits by Jan. 5.

Laryngoscopy was performed again on Jan. 10, and the inflammatory condition was seen to have receded considerably. The epiglottis was still somewhat thickened. Biopsy showed only a few poorly defined B. dermatitidis. Comparison with previous examinations showed a remarkable change in the amount and degree of inflammation and cellular changes in the epithelium.

A second course of therapy similar to that just described was initiated on Jan. 19. The initial dose of stilbamidine was 0.15 gm. and was continued daily through Feb. 1. Laryngoscopy, on Feb. 16, showed progressive resolution of the inflammatory process. Biopsy showed only a rare B. dermatitidis in scarred connective tissue. The lesions on the arm and face had dried up.

Reviewed in the Veterans Administration and published with the approval of the Chief Medical Director. The statements and conclusions published by the authors are the result of their own study and do not necessarily reflect the opinion or policy of the Veterans Administration.

From the Department of Preventive Medicine, Johns Hopkins University School of Medicine (Dr. Schoenbach and Dr. Long) and the Surgical Division, Veterans Administration Hospital, Ft. Howard, Md., and the Department of Surgery, Johns Hopkins University School of Medicine (Dr. Miller and Dr. Ginsberg).

The stilbamidine diisethionate and propamidine isethionate were supplied by Merck & Company, Inc.

[2] Schoenbach, E. B., and Greenspan, E. M.: The Pharmacology, Mode of Action and Therapeutic Potentialities of Stilbamidine, Pentamidine, Propamidine and other Aromatic Diamidines: a Review, 27: 327-377 (Sept.) 1948.

A third course of stilbamidine was begun on March 5 and continued through March 15. No toxic effects from the stilbamidine were noted. The patient had continued to improve generally. His appetite was good, and he gained 37 lb. (16.8 kg.) in weight. The esophagomediastinal and the bronchopleurocutaneous fistulas closed. Laryngoscopy performed on March 27 showed a complete recession of the inflammatory condition. The epiglottis was healed, although scarred. Biopsy from the epiglottis did not show B. dermatitidis.

SUMMARY

Two of the aromatic diamidines, stilbamidine and propamidine, have been used in the treatment of a patient suffering from advanced generalized North American blastomycosis. The immediate therapeutic effects of these compounds were excellent. A second patient with generalized blastomycosis has responded favorably to treatment with stilbamidine, and a third, ill with nocardiosis, has shown marked improvement under similar therapy. It is suggested that the diamidines be given an extensive trial in the treatment of severe yeastlike infection.

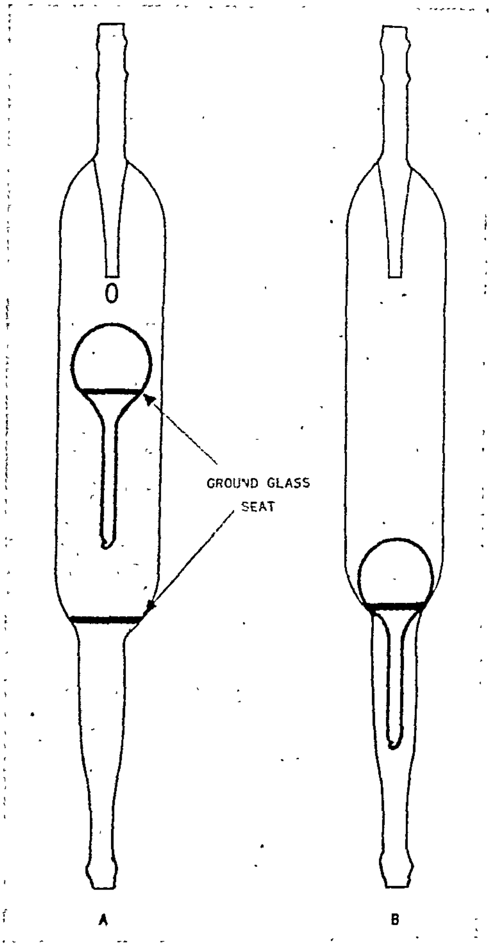
DEVICE TO PREVENT AIR EMBOLISM IN BLOOD TRANSFUSIONS UNDER PRESSURE

Charles F. Wilkinson Jr., M.D., New York

There have been several references [1] in recent journals questioning the advisability of utilizing blood transfusions under pressure because of the possibility of the blood leaving the system too rapidly and air entering the body, with resulting fatal air emboli. It is generally agreed that if the person who is introducing the air under pressure into the transfusion bottle has nothing else to do, he can stop the transfusion before air enters the vein. Recently, however, instances have been reported to me in which during the stress of operating attention was diverted from the transfusion bottle and air entered the recipient's veins, with fatal air emboli resulting.

The device presented here has been designed with the knowledge that it involves no new principle, but it is felt that its use in connection with pressure transfusions is new and can serve as a life-saving safety mechanism. As can be seen from the illustration, the device presented here is a dropping attachment which is placed between the transfusion bottle filter and the needle. The speed of the transfusion can be controlled by regulating the number of drops per minute. The only change from the usual dropping flask has been the incorporation of a glass float which has been weighted, so that it will float just below the surface of the blood in the dropping flask (fig., *A*). Also, there has been a ground glass seat made, so that, when the blood runs out (fig., *B*), there is a tight joint between the glass bulb and the dropping flask. It will be noted that in this position there is an effective seal between the air under pressure in the transfusion bottle and the patient, so that no air can enter the vein. It might be pointed out that the more pressure placed in the bottle after the blood has flowed out, the more tight and secure will be the seal caused by the float resting on the lower neck of the dropping bottle at the ground glass seat.

Since this modification of the ordinary dropping flask is made entirely of glass, it can be readily sterilized and cleaned. It can be used in an ordinary blood bank transfusion set by substituting it for the ordinary dropping bottle below the filter, or, in cases where the filter is combined with the dropping bottle, it can be added as a second dropper.



A, the normal position of the float when a transfusion is in progress. Should all of the blood be forced out of the transfusion bottle, the float will descend, forming an air-and-liquid-tight seal at the ground glass seat, as in *B*.

If a device such as this were to be incorporated in each transfusion set sent to the operating room and it were necessary to start pressure in connection with a transfusion already in progress, the safety device would already be present and would function automatically.

SUMMARY

A simple but effective device to prevent air emboli resulting from blood transfusion under pressure is presented.

BLADDER DYSFUNCTION FOLLOWING INGESTION OF PHENINDAMINE TARTRATE (THEPHORIN®)

Charles A. W. Uhle, M.D.
and
H. Roebling Knoch, M.D., Philadelphia

The symptom of difficulty in micturition, classified as a toxic manifestation induced by the antihistaminic drugs, has been infrequently observed. Rives, Ward, and Hicks[1] reported, in a brief review, that varied toxic reactions occurred with therapeutic use of antihistaminic drugs in 25% to 65% of cases. No reference was made in this report to symptoms of bladder dysfunction.

Wolfson[2] recently reported a case in which difficulty in urination followed the use of tripelennamine (pyribenzamine) hydrochloride. In September, 1948, we observed symptoms similar to those described by Wolfson following the use of phenindamine (thephorin®).

REPORT OF CASE

The patient, a white male in excellent health, 53 years of age, was seen in consultation Sept. 9, 1948, for symptoms similar to those of urinary obstruction.

On Sept. 5, phenindamine tartrate tablets, 25 mg. each, twice a day, had been prescribed by the family doctor for symptoms of hay fever. About Sept. 7, after ingesting approximately 150 mg., the patient noted that urination was difficult. The urinary stream, which had been of adequate caliber, was diminished to a trickle. It was difficult to expel the entire content of the bladder. There was associated burning on urination, and dull pain was present in the suprapubic region. There was no frequency or urgency. Nocturia was not a prominent symptom.

On Sept. 9, after the total ingestion of approximately 225 mg., medication was discontinued. Symptoms were gradually ameliorated, and normal urination was restored in four days, by Sept. 13.

Prior to this episode the patient had had no symptoms of any kind except from the rhinitis of hay fever, which phenindamine incidentally helped.

The physical examination done with special attention to the urologic tract, showed results within normal limits. The prostate was not enlarged, and the bladder was not distended. Diagnostic instrumental and roentgen procedures were not employed. Results of urinalysis were within normal limits.

The patient has been observed for more than one and one-half years and has had no further urinary difficulty. He refused a retrial of phenindamine therapy, in contrast to Wolfson's patient, in whom Wolfson was able to "prove the validity of the assumption that the distress was due to the antihistaminic agent," tripelennamine.

COMMENT

In a review of the literature on antihistamine substances, for the purpose of ascertaining the incidence of urologic symptoms of toxicity, Wolfson's case is the only one found wherein symptoms of urinary difficulty were present.

Feinberg[3] reported side reactions of burning on urination when tripelennamine was used. Kleckner[4] stated that diphenhydramine (benadryl®) and tripelennamine, given in a large clinical series, produced pronounced reactions, including urinary frequency. He mentioned that McElin and Horton of the Mayo Clinic reported urinary frequency as a noticeable effect of diphenhydramine. Feinberg referred to Arbesman, who reported burning on urination as an occasional side reaction. McGavack and associates[5] reported the incidence of toxic symptoms following phenindamine therapy to be, in descending order of frequency: oral dryness, insomnia, constipation, dizziness, jumpiness, conjunctival burning, intestinal cramps, drowsiness, weakness, and palpitations. No urologic symptoms were noted, an observation that conformed with the clinical studies of phenindamine by Boyd and associates.[6] The conclusion can therefore be drawn, after a substantial clinical trial of the antihistamines, that symptoms of urinary difficulty are not commonly encountered as a reaction to these drugs.

Dr. W. T. Strauss of Hoffmann-LaRoche, Inc.[7] has written, "We have had a few case reports from physicians who stated that a very small number of their patients complained of difficulty in urination following the use of thephorin. Just as soon as thephorin medication was discontinued the symptoms disappeared and no sequelae were observed."

We have had personal communications from two colleagues who noted this symptom complex in two male patients for whom diphenhydramine and tripelennamine had been prescribed. In the first case, an abdominoperineal resection of the rectum for carcinoma had been performed. After the immediate convalescence normal bladder function was resumed. Diphenhydramine therapy nine months later for bronchial asthma produced difficulty in urination as described in the case reported above. A latent period of two days was noted before symptoms appeared. Three days after diphenhydramine was withdrawn, normal function was restored. In the second case, a physician, with an established diagnosis of early benign prostatic hypertrophy but with no obstructive urinary symptomatology, took tripelennamine. There was a latent period of three days before symptoms of obstruction occurred. Medication was stopped. An indwelling urethral catheter was worn for three days and then removed. Four days after removal of the catheter, or 10 days after the initial dose, normal urination was restored. This patient has remained well for more than two years with no further urinary complaints. In neither of these two cases were antihistamine drugs prescribed again.

Urinary retention as a complication of antihistamine therapy is probably the result of a disturbance of the sympathetic-parasympathetic balance. Whether this is due to potentiation of epinephrine or antagonism of acetylcholine is difficult to say, although available data suggest that it may be the latter. The net result, of

course, would be the same in either case—predominance of sympathetic stimuli, resulting in relaxation of the fundus and contraction of the sphincter.

The evidence for parasympatholytic and adrenergic action of antihistamines in general has been reviewed by Loew [8] and by Meier and Bucher.[9] Both reviews mention the known antiacetylcholine action of the antihistamines. This varies considerably among compounds, with diphenhydramine and tripelennamine the most active, but is always much weaker than that of atropine.[10] Many of the antihistamines also potentiate the pressor effect of epinephrine,[11] but there seem to be little data on potentiation of other epinephrine effects, such as that on smooth muscle. The reviewers mentioned above concluded that epinephrine potentiation is not a necessary characteristic of antihistamines,[8] and this is confirmed by the antihistaminic action of some of the β-haloethylamine sympatholytics of the dibenamine® (N,N-dibenzyl-β-chloroethylamine HCl)[12] or Sy-28 type (α-naphthylmethylethyl-β-bromoethylamine hydrobromide).

It may be postulated that the symptoms of urinary difficulty following phenindamine therapy are the result of an antiacetylcholine (anticholinergic) action upon the vesical detrusor mechanism. The physiologic components involved in micturition are complex. Normal detrusor action by cholinergic stimulation implies the reciprocal action of bladder wall contraction and vesical neck relaxation. Anticholinergic response would imply the reverse action between the bladder muscle and sphincter. The symptom complex of urinary difficulty following antihistaminic therapy appears to be due to detrusor weakness associated with sphincteric spasticity.

SUMMARY

A case of difficulty in expelling the contents of the urinary bladder following phenindamine tartrate (thephorin®) ingestion is presented. This toxic symptom disappeared after the drug was withdrawn. There were no sequelae.

The detrusor muscle of the urinary bladder is contracted by cholinergic drugs. It has been postulated that phenindamine, by virtue of its anticholinergic action, can have the reverse effect upon the vesical detrusor muscle in the human by weakening detrusor contraction and causing increased tonus or spasm in the vesical sphincter. Symptoms simulating urinary retention are thus produced. Analysis of the patient's symptoms tends to corroborate this impression.

Attention is drawn to the recognition of symptoms of urinary obstruction and their relationship to the antihistaminic substances. Failure to analyze these symptoms in the male may lead to erroneous diagnosis with the possibility of unnecessary surgical intervention.

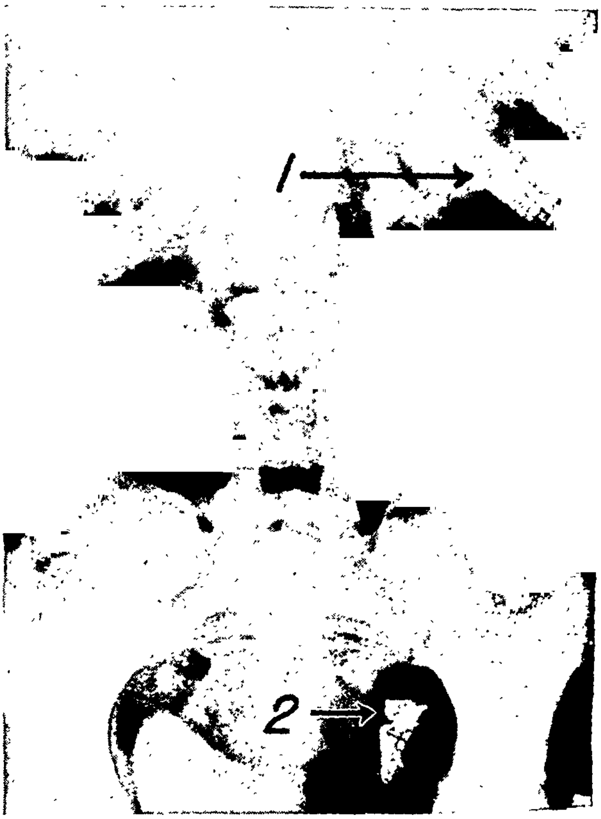
NEW DESIGN OF RADIOPAQUE ELEMENT FOR SURGICAL SPONGES

George Levene, M.D., Boston

While it is extremely rare for a roentgenologist to be called on to locate a surgical sponge, such an occasion demands a positive answer in the shortest possible time. Numerous devices have been employed to mark surgical sponges so that they may be identified on a roentgenogram. These include lead disks or metal staples fastened to the sponge, barium-impregnated thread woven into the sponge, barium-impregnated strips, and others. All of these fall short in meeting the requirement of positive identification. For example, the staple may resemble a metal clip commonly used by many surgeons for hemostasis. The small barium strip may overlie a transverse process of a lumbar vertebra, which it resembles, and not



Specimen film, which shows that *1*, even when overlying bone, the density and pattern of the sponge make it plainly visible; 2, when crumpled into a small mass, the sponge may still be identified by its pattern.

Professor of Radiology, Boston University School of Medicine, and Chief, Department of Radiology, Massachusetts Memorial Hospitals, Boston.

be recognized, and most other identifying devices may possibly be confused with something normally used at operation, or be obscured by the shadow of anatomical structures. It is obvious that to fulfill its function in this respect a marker must be plainly visible on a roentgenogram that is sometimes taken in difficult circumstances, as in an operating room, and be so eye-arresting that it is instantly identified in any part of the body.

A satisfactory solution was obtained with a new design of radiopaque element (fig.) vulcanized into the sponge so that it cannot be shaken out.[1] The opacity and pattern of this opaque element are such that it may be visualized and identified in any part of the body.

ANOMALY OF THE VENA CAVA INFERIOR

REPORT OF FATALITY AFTER LIGATION

D. B. Effler, M.D.
A. E. Greer, M.D.
and
E. C. Sifers, M.D., Cleveland

Congenital abnormalities of the vena cava are rarely of clinical significance. A review of the medical literature reveals numerous case reports of caval abnormalities based on cadaver dissection; few have been demonstrated in the living patient. Most of the anomalies encountered clinically have been associated with the vena cava superior. In the latter group, the persistent left superior and bilateral superior vena cava are most commonly described.[1] Similar anomalies occur in the inferior cava but have been reported less frequently.

Urologists occasionally find an abnormal inferior caval pattern associated with retrocaval ureter. In 1925, McClure and Butler[2] described the development of the vena cava inferior and associated anomalies. They believed that the left vena cava inferior was the last embryonic vessel to disappear and, for this reason, expected a greater number of anatomic variations associated with it. Maxwell and Erwin in 1928[3] reported on four anomalies of the vena cava inferior encountered in the dissecting room. They supplemented their report with an extensive bibliography, which included more than 50 reports of anomalies of the vena cava inferior discovered during anatomic dissection.

We have been unable to find a report of a case in which an anomalous vena cava inferior presented itself as a major surgical complication above the diaphragm. In a limited review of available anatomic records, we have found no reported instance where the hepatic vein emptied directly into the right auricle and was completely independent of the vena cava inferior. This case is presented because: (1) an unusual anomaly of the vena cava inferior existed; (2) death followed ligation and partial excision of the anomalous vessel, and (3) in retrospect it is realized that this anomaly could have been recognized and the surgical problem successfully managed.

REPORT OF A CASE

The patient was a 54-year-old white man who had been in good health until March, 1950. At that time a cough developed and he became aware of a sensation of irritation in his trachea. The cough was not productive, but was flecked with blood on several occasions. The remainder of the history was essentially noncontributory. Physical examination on June 5, 1950, revealed an unusually well-developed man whose temperature, pulse, and blood pressure were within normal limits. The significant findings were confined to the thorax. Expansion of the chest was equal bilaterally. On palpation, there was diminished tactile fremitus over the right upper thorax. Auscultation revealed a persistent rhonchus over the right anterior chest wall that could be heard on both inspiration and expiration. The left side of the chest appeared to be normal. Roentgenographic studies revealed a prominence in the right hilar region, with linear shadows of increased density extending outward from the upper part of the hilum. Laboratory studies elicited essentially normal findings.

On June 6 a bronchoscopic examination was performed. The tracheobronchial tree and vocal cords were normal except for the right main stem bronchus. A neoplasm extended into the lumen of the bronchus approximately 1 cm. below the carina at the level of the right upper lobe; the neoplasm appeared to be eroding through the posterior membranous portion of the bronchus rather than from the orifice of the upper lobe. On biopsy it was found to be an undifferentiated carcinoma, grade 4 dedifferentiation. The nature of the patient's disease was discussed, and he was advised to undergo an exploratory thoracotomy with possible eventual right total pneumonectomy.

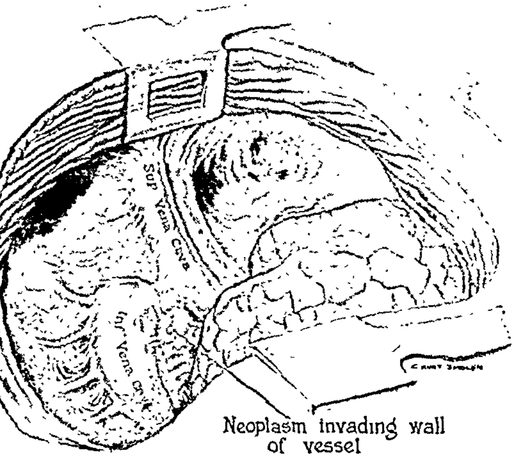


Fig. 1.—Drawing showing operative findings; the neoplasm arises from the right bronchus at the level of the upper lobe.

A right thoracotomy was performed on June 15. Inspection of the right lung demonstrated a neoplasm that appeared to be arising in the main bronchus just above the orifice of the right upper lobe. Although the carcinoma was exceedingly close to the carina, it was felt that a plastic closure of the trachea could be performed after total pneumonectomy. A number of dis-

eased lymph nodes were observed around the hilum and in the mediastinum. Frozen section examination of the excised nodes did not reveal carcinoma. The most interesting observation was a dilated vein in the normal position of the azygos vein. The vessel entered the vena cava superior in the expected position but was dilated considerably below the point of junction. The bronchiogenic neoplasm had extended through the posterior wall of the bronchus and invaded this dilated vessel. The vessel wall and the adjacent bronchus were fixed at the site of carcinomatous invasion. It was apparent that pneumonectomy could not be performed without sacrifice of the involved segment of the vein. The vein did not descend in its usual right paravertebral position but assumed a retroesophageal position at the level of the seventh dorsal vertebra and entered the left side of the chest. It could not be determined whether this vessel was unusually enlarged because of obstruction by the invading neoplasm or because of congenital abnormality. There was no question that the vessel was following an abnormal course in its approach to the left side of the chest. The possibility that it might represent the vena cava inferior was considered, but inspection of the right diaphragm and the caval hiatus revealed a normal vessel entering the right auricle at this level. It was decided to ligate this vessel above and below the point of invasion and resect a generous segment of the dilated vessel with the lung. This procedure, as well as total pneumonectomy, was carried out.

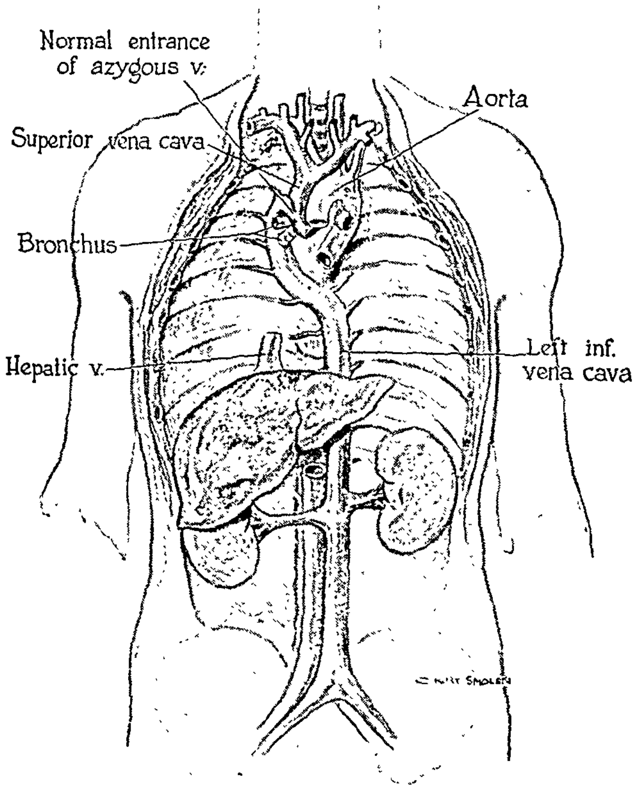

Fig. 2.—Schematic reproduction of the major veins as revealed by autopsy.

After ligation of the large anomalous vessel, the anesthetist reported a transient drop in the blood pressure, but this was interpreted as the result of a mechanical defect in the endotracheal system. The pressure was stabilized and maintained with phenylephrine (neo-synephrine®) hydrochloride and intravenous fluids. The remainder of the operation was uneventful.

The patient reacted promptly after surgery, but the tendency toward hypotension persisted. It was necessary to maintain a continuous drip of phenylephrine hydrochloride to keep the blood pressure above a renal filtration level. Approximately six hours after surgery the phenylephrine was supplemented with arterenol® and 20 cc. of adrenocortical extract in a continuous intravenous drip. The patient was catheterized at 11 p. m. on the night of operation, and approximately 100 cc. of urine containing clots and bright red blood was obtained. The patient's peripheral blood was centrifuged, and the serum was a normal color. The possibility of a severe transfusion reaction while under anesthesia was considered, but the absence of gross hemolysis in the patient's serum contraindicated this possibility. The cardiorespiratory system appeared to function satisfactorily on the first postoperative day; the patient was remarkably alert and completely free of pain or discomfort. Spinal fluid obtained 20 hr. after the operation contained blood, however, and it became apparent that the patient had suffered inadvertent ligation of an anomalous vena cava inferior, and that the presence of blood in the spinal fluid and bladder undoubtedly represented direct bleeding from the resultant high venous pressure. A program of therapy that included maintenance of blood pressure above a renal filtration level by phenylephrine hydrochloride, norepinephrine (arterenol®), and adrenocortical extract was outlined. Continuous spinal anesthesia to a level of fourth dorsal vertebra was administered at 1:15 p. m. and maintained for approximately six hours on the first postoperative day. The patient remained alert and appeared cheerful, until at approximately 7:15 p. m. he suddenly became apprehensive, cyanotic, and assumed a shocklike state. His condition deteriorated rapidly thereafter, and he died within the next hour.

Post-mortem examination was performed about two hours after death. Approximately 800 cc. of serosanguineous fluid was found in the right thorax. The mediastinum was in the mid-line and the left lung appeared essentially normal. The ligated stump of the anomalous vessel was revealed; it appeared to be dilated and tense. It was dissected along its entire course and found to enter the left mediastinum retroesophageally and to descend below the diaphragm anterior to the aorta. Intercostal veins communicated with it directly and there was no evidence of an azygous or hemiazygous system. Both renal veins communicated directly with the left-sided vena cava, as did the common iliac vessels. There was evidence of a recent massive retroperitoneal hemorrhage that had dissected the leaves of the mesentery and filled the entire retroperitoneal area with fresh clots. This was the immediate cause of death. The hepatic vein drained directly into the right auricle and in no way communicated with the vena cava inferior. The gross appearance of the hepatic vein above the diaphragm was typical of a normal vena cava inferior. The portal system was drained entirely independently of the vena cava, and did not share the severe venous hypertension produced by ligation of this vessel.

COMMENT

Although anomalies of the major blood vessels are rarely encountered during surgical intervention, their recognition is mandatory. For many years experienced surgeons have taught that large anomalous vessels encountered in the abdomen must not be ligated. Experience has apparently made the surgeon wary of the vascular anomaly.

Whereas anomalies of the vena cava inferior are probably not uncommon, they are rarely of clinical significance. We have found no report of a case in which such an anomalous vessel has been invaded by a primary carcinoma in an adjacent structure, nor have we found any description of a venous pattern in which the systemic venous return was drained independently of the portal system into the vena cava superior by a persistent left vena cava inferior. The presence of the hepatic vein prompted the erroneous diagnosis at the time of operation and resulted in the fatal technical error of ligation. In retrospect it is seen that partial occlusion of this anomalous vena cava could have been performed, with subsequent resection and reconstruction of the involved vessel wall.

ETHYLENE DICHLORIDE PLASTIC CEMENT: A CASE OF FATAL POISONING

H. B. Lochhead, M.D.
and
Henry P. Close, M.D., Coatesville, Pa.

Ethylene dichloride, a chlorinated hydrocarbon (CH_2Cl-CH_2Cl) with an aromatic chloroformlike odor, is an oily, colorless fluid slightly soluble in water. It is used in large amounts industrially as a degreasing reagent, a cholesterol extractor, a fumigator, and a solvent for oils, waxes, and rubber. It has been known to be highly toxic since its use as an anesthetic more than 100 yr. ago. Heppel and others [1] recently have described the pathological findings in laboratory animals subjected to poisoning by the chemical. Despite its widespread use industrially it has not produced a fatality in any of the reported cases of poisoning by inhalation. On the other hand, ingestion is generally followed by death. Ten such cases have been found in the world literature.[2] However, only one of these cases is reported in the American literature. The substance was mistaken for liquor by the majority of the victims. They rapidly became nauseated, vomited, were prostrated, and lapsed into unconsciousness. Death resulted four and one-half to 91 hr. following ingestion. The longest period of survival occurred in those having gastric lavage soon after the ingestion. Findings in the cases that came to autopsy generally included acute hemorrhagic gastritis or enteritis, congestion of the principal viscera, toxic hepatitis and nephrosis, and microscopic hemorrhages throughout the brain.

Ethylene dichloride readily dissolves certain plastics; the use of this chemical as a plastic cement is common not only in industry but in occupational therapy shops and in homes where work with plastics is a hobby. Because of its increasing use in these areas, we believe this report of a fatality following the ingestion of ethylene dichloride plastic cement is indicated.

REPORT OF A CASE

A white man, age 50, had been hospitalized for schizophrenic psychosis continuously since 1938. During his course in the hospital he regressed considerably, manifesting hallucinations and untidiness. He exhibited pica, ingesting various foreign substances, such as cigaret butts, papers, buttons, and other detritus which he scavenged. On Aug. 1, 1950, the patient was in an occupational therapy shop of the hospital. Despite the watchfulness of the therapists and aides, the patient was able successfully to secrete on his person a 240 ml. (8 oz.) bottle of plastic cement (ethylene dichloride) and surreptitiously to drink approximately 30 ml. (1 oz.) of the material. Subsequent investigation indicated that this material was ingested sometime between 9:30 and 9:50 a. m. However, the symptoms were not manifested until 10:10 a. m., when the patient was found lying unconscious on a bench in the recreation area of the hospital. Examination by a physician at 10:15 a. m. showed that he had vomited dark fluid containing tin foil and cigaret butts. He was transferred immediately to a medical ward, where he rapidly became cyanotic and unconscious, with dilated, fixed pupils. Signs of acute pulmonary edema were present. Despite intensive emergency therapy, respiratory difficulty increased and a tracheotomy was performed at noon. During this interim the patient frequently vomited thick, darkred fluid having the characteristic aromatic odor of ethylene dichloride and containing small, oillike globules. The patient's condition continued to deteriorate; consciousness was not regained and death supervened at 7:15 p. m. the same day, approximately 10 hr. after ingestion of the poison. Permission for autopsy was obtained, and the examination performed. The principal findings were diffuse hemorrhagic gastritis, bilateral pulmonary congestion, acute necrotizing bronchiolitis and bronchitis, acute toxic nephrosis, diffuse hepatic necrosis, and hyperemia of the brain with scattered perivascular hemorrhages in the pons. The thick bloody fluid found in the stomach and the bladder urine had the characteristic odor of ethylene dichloride. Samples of blood, liver, and kidney tissues were subjected to distillation; the distillate contained no aromatic hydrocarbon.

COMMENT

The toxicity of ethylene dichloride and similar plastic solvents apparently is not well recognized by workers in plastics, particularly at the occupational therapy and hobby level. Unfortunately, in our own instance the product was delivered from the jobber with a plain label bearing only the jobber's name and the name of the chemical. No warning of any kind appeared on the label to indicate the toxicity of the product.

Although only one other case of a fatality resulting from the ingestion of ethylene dichloride has been reported in the American literature, the widespread and increasing use of this type of plastic cement carries with it implications of serious import should proper warning of its poisonous nature not be indicated on containers in which this chemical is merchandized. Particular reference is made to the known predilection of children for experimenting with and swallowing unknown liquids when they are readily available.

Thyrotoxicosis.—Surgical removal of the thyroid gland still remains the major therapeutic measure in the vast majority of patients with the conventional type of Graves' disease, but the success of the operation depends to a large degree on the quality of the preoperative preparation. Up to but a few years ago this attempt at preparation involved several weeks or even months of hospitalization, the administration of iodine, and anxious waiting for the day when a remission would be sufficiently advanced to reduce the hazard of surgical intervention. Even then, failures to secure satisfactory remission were numerous and postoperative thyroid storms were frequent. The use of propylthiouracil together with iodine has materially changed the outlook. With these measures adequate preoperative preparation is more rapid, more certain and more complete. It can be carried out with the patient in the ambulant state. Admission to the hospital may be postponed up to a few days prior to the date set for the operation. Postoperative thyroid storms have practically vanished. In centers best equipped for the management of Graves' disease mortality from thyroidectomy has virtually disappeared.—Harry Gold, M.D., Management of Thyrotoxicosis, Conference on Therapy, *American Journal of Medicine*, April, 1951.

COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION

REPORT OF THE COUNCIL

The Council on Physical Medicine and Rehabilitation has authorized publication of the following report.

The Council wishes to express its appreciation for the valuable cooperation of the Advisory Committee on American Health Resorts for its expert services. The Committee members are Drs. F. A. Hellebrandt, M. B. Jarman, Walter S. McClellan and Euclid M. Smith. Howard A. Carter, *Secretary.*

THE HEALTH RESORT IN THE MANAGEMENT OF CHRONIC DISEASE

A health resort is an institution which gives major attention to the systematic use of climatic and other natural therapeutic resources, including mineral waters and peloids, with which it is endowed by virtue of geographic location. Various sections of the United States are subject to widely different climatic conditions, some of which offer therapeutic advantages not obtainable elsewhere. All types of mineral waters thought to have therapeutic value are found in this country.[1] How gifts of nature may be utilized for healing purposes in institutions especially designed to expedite their application has been discussed in the growing literature on rehabilitation.[2] Rusk's [3] concept of the third phase of medical care, which carries the patient beyond diagnosis and definitive treatment to full restoration of function, has greatly enlarged the therapeutic possibilities of these facilities.

Recent advances in the clinical aspects of climatic physiology [4] are furnishing statistical proof for suppositions which have persisted since the days of Hippocrates. It has long been known that the mean environmental temperature affects the energy level of populations [5] and that meteorologic strain influences the course of disease.[6] In general, the warmth of tropical and sub-tropical regions tends to be debilitating. The evidence now accumulating suggests that this may depress vitality and secondarily affect susceptibility to infection. On the other hand, the more invigorating climate of the middle temperate zone autonomously augments activity and this brings in its wake a heightened incidence of degenerative and metabolic ailments. Thus climatic environment appears to have a sufficiently direct influence on the energetics of human behavior to make weather a factor of importance in the management of disease and the maintenance of health, especially that of those who have lost the physiologic resilience characteristic of youth.

Common to the experience of all physicians is the fact that when conservative treatment in the home environment fails, relocation of the patient may have health advantages attributable in part at least to the climatic factor. Temporary migration to a locality in which meteorological conditions are favorable may be sufficiently restorative to reestablish tolerance to environmental strains previously disabling. How much of the effect is due to the therapeutic advantages of change of scene, which are recognized universally, is a question of more academic than practical importance.

The mineral waters and peloids which have been used most extensively for therapeutic purposes in recent times are those found in geographic regions endowed by nature with scenic beauty, a favorable temperature and altitude, an abundance of sunshine, and relative freedom from storms. Mineral waters rank among the most ancient remedies used for the alleviation of the disabling concomitants of chronic disease. They have been held in high esteem by all races of mankind in all ages. Empirical evidence in support of their value has been recorded in hundreds of papers and monographs. What proportion of the sum total of the effect of spa therapy is attributable to the mineral waters per se, is also open to speculation. Climatic factors play a part, as does the hygienic regimen with which spa therapy is associated traditionally.

Chronic disease is usually accompanied by diminution in physical activity, which may have either an organic or psychogenic basis. This in itself may then give rise to sufficient deterioration in general fitness and vitality to affect adversely the course of the primary ailment. The resumption of self-sustaining activities by the ambulant chronically ill patient may be expedited significantly by temporary residence in a health resort or spa. Change in scene and freedom from the stress of home or occupational responsibilities is one of the major components of the so-called spa or health resort regimen. When this is combined with dietary control and a balanced program of rest, prescribed exercise increasing progressively in severity, and healthful diversional activities, the machinery of the body as a whole soon operates at a level conducive to maximal restoration of residual function. Association with others actively interested in rehabilitation and committed to a way of life believed to be essential to its attainment, is also of unquestioned value.

Mineral waters are prescribed in the form of baths, packs, inhalation or "drinking cures." Their temperature, mineralization and gaseous constituents depend on the geologic formations and strata through which they flow and the depth from which they rise. Their physicochemical properties determine their therapeutic use. The manner in which they are administered influences their physiologic effects. External applications are used primarily either for their hydrothermic or hydrokinetic influence. Modern equipment permits precise control of both temperature and pressure of the waters used. Peloids provide an excellent medium for conduction heating because of their plasticity, low specific heat, and poor conductivity. They cool slowly and temperatures up to 50 C. are tolerated. Frequently spas have available some forms of classical physical therapy. Others also provide occupational therapy. The judicious application of natural resources of therapeutic value combined with other physical remedies as indicated, retreat under medical supervision, and life in a healthful environment, must, in the aggregate, form a powerful triad of adjuvants, useful in the management of the chronically ill patient.

The Committee on American Health Resorts of the Council on Physical Medicine and Rehabilitation of the American Medical Association assists the physician by listing climatic and mineral spring facilities believed to have value in the treatment of the sick and disabled. To be accepted for listing a health resort must be located where natural healing agents or special climatic conditions are found, be operated under medical supervision, have a physical plant suitable for administration of treatment with the natural agents, and have available accessory forms of physical medicine under proper supervision. The files of the Council contain information about the chemical composition of many mineral waters now used therapeutically, the qualifications of medical and technical personnel affiliated with health resorts, the type of accommodations available, the average patient load, the conditions treated and the season of year considered most advantageous to the patient from a climatic viewpoint. The Council's "Handbook of Physical Medicine and Rehabilitation" [7] classifies the mineral waters, presents the scientific basis of health resort therapy, and discusses indications for its use. A health resort or spa selected from the list recommended by the Committee assures the referring physician that the patient will receive supervision from a colleague versed in all aspects of the special forms of therapy utilized in such institutions. He will be certain that treatment is administered only by specially trained technical assistants who work under medical supervision. Direct referral is the best procedure to follow.

A full exchange of information about the patient by the family doctor and the health resort specialist insures continuity of control and avoids duplication of laboratory studies deemed essential to proper management.

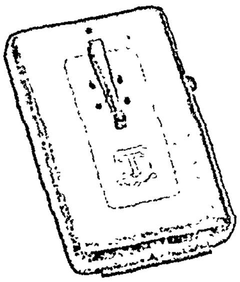
Increasing interest in chronic disease as a primary medical problem in an aging population indicates that new types of medical service must be made more generally available if residual functional capacities are to be maintained at levels capable of meeting the stresses of daily living at all economic levels. Increased utilization of the nation's natural climatic and mineral water resources is one method of attaining this objective. The possibilities inherent in their incorporation in an expanding system of rehabilitation centers challenges the imagination and should be investigated by all who are confronted with the problem of evolving a rational method of meeting the health needs of the ambulant chronically ill patient.

The Council on Physical Medicine and Rehabilitation has authorized publication of the following reports.

Howard A. Carter, *Secretary.*

TONAMIC HEARING AID, MODEL 50, ACCEPTED

Manufacturer: Tonamic, Inc., 12 Russell St., Everett 49, Mass.



Tonamic Hearing Aid, Model 50

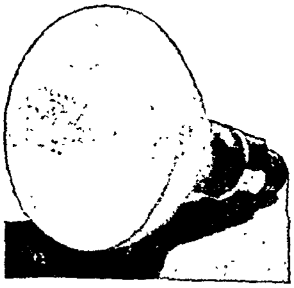
The Tonamic Hearing Aid, Model 50, is an electric hearing aid of conventional design. Excluding projections, the case measures 90 by 58 by 20 mm., and without batteries the device weighs 85 gm.

Evidence from sources acceptable to the Council indicated that this device was satisfactory in construction and performance. The Council on Physical Medicine and Rehabilitation voted to include the Tonamic Hearing Aid, Model 50, in its list of accepted devices.

SYLVANIA SUN LAMP, MODEL RS, ACCEPTED

Manufacturer: Sylvania Electric Products, Inc., 60 Boston St., Salem, Mass.

The Sylvania Sun Lamp, Model RS, is a completely self-contained bulb which can be screwed into the standard light-socket. No transformer or reflector is needed, as both are contained within the bulb. It will not operate on direct current, but requires 110 to 125 volts of 50 to 60-cycle alternating current. It draws 275 watts. The firm states that, at an average exposure of 5 to 30 minutes each, it should furnish about 600 applications. After an average of 600 applications, even though the lamp may still light, the ultraviolet output is likely to have become so low that replacement with a new bulb is advisable. A package of six lamps measures 28 by 69 by 46 cm. (11 by 27 by 18 in.) and weighs 6 kg. (13 lb.).



Sylvania Sun Lamp, Model RS

Evidence from sources acceptable to the Council indicated that this lamp satisfied the published minimum requirements of the Council for the acceptance of sun lamps. The Council points out that ultraviolet radiation is effective only on skin that is actually exposed, that the radiation from sun lamps is not recommended as illumination for reading, and that the eyes, if not protected from such radiation by goggles, should at least be kept closed. The Council on Physical Medicine and Rehabilitation voted to include the Sylvania Sun Lamp, Model RS, in its list of accepted devices.

SANDERS OSCILLATING BED (VASOSCILLATOR) ACCEPTED

Manufacturer: American Hospital Supply Corporation, 2020 Ridge Ave., Evanston, Ill.

The Sanders Oscillating Bed was originally designed to aid the circulation in peripheral vascular disease and was accepted by the Council for this purpose. The apparatus is described in an announcement of acceptance published in The Journal Nov. 26, 1938. In May, 1950, the manufacturer requested further consideration of the apparatus as a means for giving artificial respiration.

The bed measures 78 by 91 by 210 cm. (30¼ by 36 by 82½ in.) in height, width, and length, respectively, and weighs 158 kg. (389 lb.). Crated for shipment it measures 88 by 109 by 223 cm. (34¾ by 43 by 88 in.) and weighs 240 kg. (530 lb.). The foreign shipping weight is 309 kg. (680 lb.). The accessories included in the weights given are as follows: Electric cord from motor to outlet (complete with on-and-off switch and plug), crank handle to adjust spring bottom to different positions, and mattress stops for head and foot ends. The motor is driven by 60-cycle alternating current at 110 volts and draws about 300 watts.

Sanders Oscillating Bed (Vasoscillator)

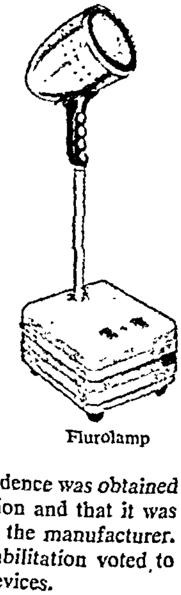
Evidence submitted to the Council indicated that the apparatus could be used for limited periods of time in giving artificial respiration, for instance, to patients with poliomyelitis, provided the patient were not in a stage where muscular tenderness made the motion intolerable. The Council on Physical Medicine and Rehabilitation voted to recognize the potential usefulness of the Vasoscillator as an aid to respiration in poliomyelitis and similar conditions in addition to its previously recognized usefulness in circulatory diseases, with the understanding that the manufacturer will not represent it as complete equipment for handling all types of respiratory failure.

FLUROLAMP ACCEPTED

Manufacturer: Hanovia Chemical & Mfg. Co., Special Products Division, 100 Chestnut St., Newark 5, N. J.

The Flurolamp is a source of ultraviolet radiation designed for use in diagnosis. The radiation is also described as Black Light. It closely resembles Wood's Light, which is filtered through Wood glass containing nickel oxide, but differs in that the radiation of the Flurolamp is filtered through a glass called Ultra 5872, which is heat-resisting and transmits less of the shorter ultraviolet radiation. The Flurolamp is provided with a roughly parabolic reflector and is mounted on a low stand which can be set on a table and which contains the switch and other necessary electrical apparatus. The housing of the lamp bears a handle by which it can easily be lifted off the stand and moved and manipulated freely.

Unpacked, the article measures 52.5 by 30 by 20 cm. (21 by 12 by 8 in.). Packed for shipment it measures 34 by 38 by 39 cm. (13½ by 22¾ by 15½ in.) and weighs 11.3 kg. (25 lb.). For operation it requires a 60 cycle alternating current at 110 volts.



Flurolamp

From sources acceptable to the Council, evidence was obtained that this device was of satisfactory construction and that it was useful for diagnostic purposes as claimed by the manufacturer. The Council on Physical Medicine and Rehabilitation voted to include the Flurolamp in its list of accepted devices.

HORMONAL CEREBRAL VASOPRESSOR SUBSTANCE

Essential hypertension is believed to be of multiple etiology, involving neurogenic, cardiovascular, endocrine, and renal factors. Binet and Burstein [1] demonstrated that centripetal stimulation of the vagus in a dog introduces into the blood of the animal a vasoconstrictor substance which is manifested by a rise in pressure in the blood vessels of the denervated leg of the dog perfused with its own blood or blood from another dog. Injection of "prosympal," or 883F (diethylamino-methyl-3-benzodioxane), a synthetic sympathicolytic drug, did not reverse the peripheral vasoconstriction in the same dog. They argued that, if the rise in pressure following centripetal stimulation of the vagus depended solely on discharge of epinephrine, the increased pressure in the blood vessels of the denervated leg should have been abolished by the action of the sympathicolytic drug. This irreversibility of the peripheral constriction by a sympathicolytic drug demonstrates the presence of a vasopressor substance of cerebral origin.

At least three pressor substances are known to originate in nerve tissues, according to Taylor, Page, and Corcoran.[2] These are epinephrine, arterenol, and vasopressin (pitressin®). These authors believe they have demonstrated the existence of still another pressor substance. They have isolated in a dog the circulation of the central nervous system cephalad to the fifth cervical vertebra and perfused the animal with the blood of a donor dog. The effluent jugular blood of the head of dog A was returned by anastomosis to the jugular vein of dog B. Both vagi of dog A were cut in the neck, and the central end of one or other or both vagi of dog A were stimulated with a sinusoidal current of an intensity of about 50 ma. This resulted in a slow rise of arterial pressure in dog B, which slowly disappeared after the stimulation was stopped. In still another experiment, the spinal cord distal to the sixth cervical segment was exposed by laminectomy and was pithed. Test doses of epinephrine and arterenol were given, after which the vagi were stimulated. This stimulation caused a gradual rise in arterial pressure which persisted for five to 10 minutes after stimulation was stopped. Tetraethylammonium chloride in doses of 5 mg. per kilogram augmented the pressor action of epinephrine and arterenol. Administration of piperoxan hydrochloride during the periods of vagus stimulation resulted in augmentation of the pressor response. Reubi [3] demonstrated that 1-hydrazinophthalazine (C-5968) is an effective hypotensor and a renal vasodilator. This has been confirmed by Page and McCubbin and by Schroeder. The drug, according to these investigators, causes profound and prolonged lowering of arterial pressure in dogs with chronic neurogenic and renal hypertension. Taylor and associates [2] found this substance effective in widely differing forms of hypertensive disease. They also found, in their experiments with vagus stimulation in the dog, that three successive intravenous injections of 1-hydrazinophthalazine in doses of 1 mg. per kilogram abolished the pressor effect of the centripetal vagus stimulation.

Rapport and associates [4] demonstrated a pressor and vasoconstrictor substance formed during the clotting of blood. Because it is derived from serum and because its action is that of constriction, they called it serotonin. Taylor and co-workers believe that the substance they have demonstrated by vagal stimulation is of cerebral origin and that it has a common property with serotonin. They feel that participation in essential hypertension of a pressor substance of cerebral origin, unaffected by agents that wholly block adequate doses of epinephrine and arterenol, would explain some of the paradoxes of our knowledge of the altered physiology of this disease. This might explain, for example, the fact that patients with so-called neurogenic hypertension are frequently not benefited by extensive lumbodorsal sympathectomy, whereas, were their disease dependent only on vasomotor mechanisms, the results should be good. Since 1-hydrazinophthalazine is active in etiologically distinct types of hypertension and since it acts by inhibiting a cerebral vasopressor substance, the cerebral vasopressor substance may participate in varying degrees in more than one form of hypertensive disease.

These observations suggest that the brain can, on appropriate stimulation, act as an endocrine organ and release a hormonal pressor substance into the blood. The conclusion is in accord with the view held by Claude Bernard that every organ is in some respect endocrine.

CHONDROITIN SULFATE

Chondroitin sulfate is one of the important constituents of cartilage, since it is believed by many in the field that this tissue is made up mainly of chondroitin sulfate and the insoluble protein collagen. Chondroitin sulfate is a nonreducing polysaccharide composed of equal parts of an amino sugar and acetic, sulfuric, and glucuronic acids. The sulfuric acid is present in an esterified form. Dziewiatkowski[1] showed that administration of radioactive sulfur in the form of sulfate caused a deposition of radioactivity in the knee-joint cartilage of weanling rats. In addition the radioactivity was concentrated in the chondroitin sulfate isolated from the cartilage.

More recently Dziewiatowski[2] reported the effect of thiouracil and thyroxine in the deposition of radioactive sulfate sulfur in the knee-joint cartilage of rats. He found that pretreating the animals with thiouracil reduced the uptake of radioactive sulfur in the cartilage of these animals. On the other hand, the effect of thiouracil in decreasing the deposition of sulfur in cartilage could be counteracted by the administration of thyroxine. Also, through the use of isotopes, the approximate mass of chondroitin sulfate deposited in the knee joints of the rats in 24 hours could be calculated. The period chosen in this work was between the 7th and 8th day of life in the suckling rat. Approximately 0.134 gm. of chondroitin sulfate was formed per 100 gm. of cartilage during this period. This is probably the first instance in which the actual rate of formation of chondroitin sulfate has been determined. It is of importance to obtain more information concerning all phases of the origin and degradation of this most interesting mucopolysaccharide, since it is widely distributed in tissue and probably undergoes many changes during various pathological states.

CONTRIBUTORS TO THE AMERICAN MEDICAL EDUCATION FOUNDATION

American medicine, industry, labor, agriculture, and many other groups are presently joined in a movement to forge a practical program for the support of medical education. The members of the medical profession are making their contributions through the American Medical Education Foundation. The money thus collected is channeled into the National Fund for Medical Education, which distributes these funds, along with the donations of others, to the nation's 79 medical schools.

The contributions of many organizations interested in the future of medical education have done much to get this movement started. However, of equally great import have been the individual gifts by American physicians. To these individuals, the Directors of the American Medical Education Foundation extend gratitude—for their monetary contributions and for the example they are setting for others.

Elsewhere in this issue (page 1329) is published a list of those who have contributed to the American Medical Education Foundation as of July 5, 1951. The listing is by states, with the total contributors from each state indicated. Organizations and lay persons making contributions are also named. Additional lists of donors will be printed from time to time in THE JOURNAL.

A NEW BACTERIAL VITAMIN

During the past decade, microbial mutants have proved valuable tools for study of the mechanisms of chemotherapeutic action and of the biochemical alterations responsible for drug resistance in micro-organisms. Recent experiments by Davis illustrate the type of data that may be obtained from such studies. Nutritionally deficient mutants of Escherichia coli were isolated by an ingenious procedure[1] based on the fact that, while penicillin will destroy actively growing bacteria, it has little effect on resting organisms.[2] Mutants produced by exposing colonies of Esch. coli to ultraviolet irradiation were cultivated on a penicillin-containing minimal medium in which glucose, lactose, ammonia, and sulfur were the sole sources of carbon, nitrogen, and sulfur. Amino-acid-requiring mutants remained dormant and were unaffected by the penicillin but were rendered as sensitive as the nonmutants when the amino acids essential to their growth were added. Among the mutants isolated was one which grew slowly on a mixture containing tyrosine, phenylalanine, tryptophane, and paraaminobenzoic acid.[3] Growth of this mutant was accelerated by the addition of either an excess of paraaminobenzoic acid or of shikimic acid, previously shown to be precursor of the above four metabolites. It was postulated, therefore, that the mutant required a fifth metabolite which could be readily formed from shikimic acid and, less readily, from paraaminobenzoic acid. A substance with the activity of the postulated metabolite was isolated from culture filtrates of parent wild type Esch. coli and was subsequently shown by paper chromatography and by biological assay to be identical with the aromatic compound parahydroxybenzoic acid. The high order of activity of this compound led Davis to suggest that it be considered as a bacterial vitamin.

Preliminary studies have shown that parahydroxybenzoic acid completely overcomes the inhibitory effects of excessive amounts of paraaminobenzoic acid on a wild type Esch. coli in a 1:200 ratio and partially overcomes the inhibitory effect of the analogue, 4,4′-dihydroxydiphenyl sulfone. However, neither this latter compound nor paraaminobenzoic acid will produce complete inhibition of parahydroxybenzoic acid unless traces of l-aspartic acid are added, although high concentrations of aspartic acid alone do not affect the growth of the bacteria.[4] It has further been shown that parahydroxybenzoic acid reverses the static effect of paraaminobenzoic acid on Rickettsia under certain circumstances.[5] These reports are of considerable theoretical and practical interest, since they indicate that the mechanism of the chemotherapeutic action of paraaminobenzoic acid against the rickettsial infections may be by competitive inhibition and they suggest the importance of testing the chemotherapeutic action of other analogues of the newly discovered vitamin.

ORGANIZATION SECTION

ABSTRACT OF MINUTES OF MEETINGS OF BOARD OF TRUSTEES IN ATLANTIC CITY, N. J., JUNE 8-14, 1951

APPOINTMENTS

The following appointments were made by the Board of Trustees:

Dr. Carl M. Peterson to attend the Tenth International Congress of Industrial Medicine in Lisbon, Portugal, Sept. 9-15, 1951, to become a member of the United States delegation on the Commission Internationale Permanente pour le Medecin du Travail, to serve on the panel on social and occupational health of the World Health Organization and to confer with members of the Occupational Health Committee of the British Medical Association and officers of the Association of Industrial Medical Officers on the report issued by the Committeee on Enquiry on Industrial Health Services (Dale Committee).

Dr. Ray O. Bjork of Butte, Mont., to succeed Dr. Glenville Giddings, who is ineligible for reappointment, for a term of four years on the Joint Committee on Health Problems in Education of the American Medical Association and the National Education Association.

Dr. Truman Terrell, Fort Worth, Texas, as the fifth member of the Committee on Public Relations Policy of the American Medical Association.

Dr. W. W. Bauer to the executive committee of the National Committee for Traffic Safety.

Dr. Howard Gray and Dr. Donald Smelzer to succeed themselves for a three-year term on the Commission for the Improvement of the Care of the Patient.

Dr. T. P. Murdock to serve as special adviser to the Committee on Immunization of the National Foundation for Infantile Paralysis, Inc.

Dr. Donald Dukelow to serve as a member of the Elizabeth S. Prentiss Award Committee for 1951 of the Cleveland Health Museum to recommend to the trustees of the Museum a recipient for the 1951 Prentiss Award in Health Education.

Dr. George F. Lull to membership on the National Advisory Board of the All-American Conference to Combat Communism of the American Legion.

Dr. Austin Smith to the Committee on Consultants for the Study of the Indexes to Medical Literature of the Army Medical Library.

Dr. Richard L. Meiling to the Council on National Emergency Medical Service as of July 1.

Dr. Oscar B. Hunter as Chairman of the Committee to Entertain Foreign Guests at annual and clinical sessions of the Association.

Dr. L. W. Larson on the Medical Policies and Procedures Committee of the American National Red Cross Blood Program.

COMMITTEE ON MEDICAL MOTION PICTURES

An appropriation was authorized by the Board to permit of a preliminary investigation to be conducted by the Committee on Medical Motion Pictures to ascertain a satisfactory method of determining the relative effectiveness of motion pictures in medical teaching.

FOOD LAW INSTITUTE

Authorization was given to Dr. James R. Wilson, Secretary of the Committee on Foods and Nutrition, to accept the invitation from the Food Law Institute to become public trustee of that organization.

SCIENTIFIC EXHIBITS

The following invitations to exhibit at meetings were accepted by the Board:

Michigan State Medical Society, Grand Rapids, Sept. 26-28.

American Dental Association, Washington, D. C., Oct. 15-18 (exhibit and motion picture).

CIVIL DEFENSE CONFERENCE

The Board of Trustees approved a request that arrangements be made for the holding of a meeting on civil defense in the near future.

CLINICAL SESSIONS

Dr. Walter Scott was appointed Chairman of the Local Committee on Arrangements for the Clinical Session of the Association to be held in Los Angeles, Dec. 4-7, 1951.

Miami was selected as the place for the 1954 Clinical Session of the American Medical Association.

RADIO BROADCASTING AND TELEVISION

The Board approved acceptance of the invitation from President Truman's Committee on Accident Prevention, a subsidiary of the Department of Labor, to cooperate in a documentary broadcast on accident prevention.

Authorization was given for the holding of a conference in the early fall of 1951 of representatives of national television agencies to explore the educational implications and possibilities of television.

The Board also voted that congratulations be sent to the National Broadcasting Company on the occasion of its 25th anniversary.

"THE KEY TO PEACE"

The Board authorized sending the book "The Key to Peace," by Clarence Manion, to all members of the House of Delegates.

NATIONAL FIRE PROTECTION ASSOCIATION

The continued membership of the American Medical Association in the National Fire Protection Association was approved by the Board.

NATIONAL FOUNDATION FOR INFANTILE PARALYSIS, INC.

The Board voted to endorse a proposal from the National Foundation for Infantile Paralysis, Inc., which would further the cooperation between the chapters of the Foundation and organized medicine. A letter on this subject is being sent to the secretaries of all state medical societies.

INTERNATIONAL POLIOMYELITIS CONGRESS

The use of the name of the American Medical Association as an endorser of the Second International Poliomyelitis Congress, to be held in Copenhagen, Sept. 3-7, 1951, was approved by the Board.

Dr. Austin Smith was selected as one of the representatives of the association to attend the Congress; the other delegate will be chosen at a later date.

ALL-AMERICAN CONFERENCE TO COMBAT COMMUNISM

A contribution was made by the Board for the furtherance of the work of the American Legion's All-American Conference to Combat Communism.

CONFERENCE OF EDITORS OF STATE MEDICAL JOURNALS

The Board authorized the holding of a conference of editors of state medical journals at a time to be arranged by the Secretary and General Manager and the Advisory Committee to the State Journal Advertising Bureau.

REORGANIZATION OF BOARD

Following the adjournment of the House of Delegates on Thursday, June 14, the Board of Trustees reorganized and elected the following officers, committees and representatives:

Board of Trustees: Dr. Dwight H. Murray, Chairman; Dr. Gunnar Gundersen, Vice Chairman, and Dr. E. S. Hamilton, Secretary.

Executive and Finance Committees: Dr. Gunnar Gundersen, Dr. E. S. Hamilton and Dr. W. B. Martin.

Committee on Scientific Exhibit: Dr. E. J. McCormick, Chairman; Dr. L. W. Larson, and Dr. T. P. Murdock.

Representative on Council on Medical Service: Dr. David B. Allman.

Representative on Council on Industrial Health: Dr. E. J. McCormick.

Representative on Committee on Rural Health: Dr. L. W. Larson.

The Board of Trustees considered several other matters presented to it and the action taken on these will be found in its supplementary reports in the *Proceedings* of the House of Delegates (THE JOURNAL, June 30 and July 7, 1951).

CONTRIBUTORS TO THE AMERICAN MEDICAL EDUCATION FOUNDATION

Following are the names of all individuals and organizations who have contributed to the American Medical Education Foundation as of July 1, 1951.

PHYSICIANS

MEDICAL LEGISLATION

FEDERAL

Armed Forces Reserve Act of 1951

H. R. 4667, introduced by Representative Brooks of Louisiana, proposes to reorganize the reserve components of the Armed Forces. This bill resulted from the demand of the House Armed Service Committee for a better reserve program. It was submitted by the Defense Department and proposes to rewrite the laws pertaining to the reserve programs of the military services. In the recently enacted Public Law No. 51 (amending the Selective Service Act), it is contemplated that approximately 850,000 persons will enter the military services annually and that eventually a like number will complete active service annually. Persons completing active service will be required to continue in a reserve status for a combined service period of eight years. This proposed legislation would establish, within the seven official reserve components, three groups, which would be called to duty in the following order, depending on the nature of the emergency: (1) ready reserve, (2) stand-by reserve, and (3) retired reserve. Two American Medical Association Councils are interested in the provisions of this legislation; the Council on National Emergency Medical Service, because of liability of physicians to serve, and the Council on Medical Service, because of provisions dealing with medical care and periodic examinations for the contemplated large reserve force.

Federal Aid to Medical Education

Senator Hill of Alabama introduced an amendment to S. 337, which would amend the Public Health Service Act and the Vocational Education Act of 1946, to provide an emergency five-year program of grants and scholarships for education in the fields of medicine, osteopathy, dentistry, dental hygiene, public health, and nursing. The declaration of policy in S. 337 states that the five-year emergency program proposed is essential to meet "immediate and prospective requirements of the Armed Forces. . . ." This amendment would add the words "and the Veterans Administration" after the words "Armed Forces." The amendment was not referred to a committee but will be considered on the floor in the event S. 337 is acted on by the Senate membership.

MEDICAL NEWS

CALIFORNIA

Gold Headed Cane Ceremony.—The 14th Ceremony of the Gold-headed Cane at the University of California School of Medicine, San Francisco, was held June 5. The award is made annually to the outstanding senior medical student chosen by his fellow students and by faculty members for having in greatest measure the qualities of "a true physician" and for showing "the greatest interest in the care of his patients during the clinical year." An eminent physician is selected to give an address on the occasion, and he too receives a gold-headed cane. The winner of the honor in 1951 was Charles J. Carman, while John Lewis Linville and George W. Smith received honorable mention. The guest speaker was Dr. Roger Irving Lee, Boston, a former president of the American College of Physicians and of the American Medical Association. The award, a yew-wood cane with an engraved golden handle, is modeled after the famous gold-headed cane which was immortalized in Macmichael's book and which now reposes in the Royal College of Physicians in London. The original cane passed successively from its first owner, Radcliffe, in the 15th century, through the hands of other illustrious British physicians. The gold-headed cane of California passes in like manner from winner to winner, and a second cane from speaker to speaker. The ceremony was first inaugurated in 1939 by Dr. William J. Kerr, professor of medicine and chairman of the division of medicine.

COLORADO

Honor Five Fifty-Year Practitioners.—Five San Juan Basin physicians, whose combined service to the people of southwestern Colorado totals 250 years, were honored June 2 by the San Juan Medical Society at a testimonial banquet in Durango. The five physicians are Drs. Royal W. Calkins, Cortez; Carl Lefforge, Ignacio; Jay R. Trotter, Mancos, and Wordsworth M. Elliott and Benjamin J. Ochsner, both of Durango. A bronze plaque was presented to each of the men honored.

ILLINOIS

Blumberg Memorial Blood Bank.—The Jacob Blumberg Memorial Blood Bank of the Lake County Medical Society has been organized to supply all the hospitals in Lake County. Organization of the blood bank was aided by a gift of $10,000 from the Blumberg family of Waukegan. Families in the county are signed up as a unit with the promise that one member of the family will give one pint of blood when requested by the bank. In return for this each family is guaranteed all the blood it may need at any time without the necessity of replacing the blood or paying for it. Only the usual hospital service charge will be made. Blood is now distributed to each hospital in the county and is available at all times. The distribution of blood to the hospitals is carried out by the sheriff's office, which, in addition, has facilities always available to carry blood for emergencies.

Chicago

Society News.—At the May meeting of the Chicago Neurological Society in Manteno the following officers were elected for the coming year: Dr. John Martin, president; Dr. Hugh T. Carmichael, vice president; Dr. Joseph A. Luhan, councilor, and Dr. Leo A. Kaplan, secretary.

Personals.—Dr. Nathaniel S. Apter has been promoted to the rank of associate professor of psychiatry at the University of Chicago.——Robert M. Cunningham Jr., formerly managing editor of *Hygeia* and since 1945 managing editor of *Modern Hospital*, has been appointed editor of the latter publication.

Hektoen Memorial Fund.—Creation of this fund at the Hektoen Institute for Medical Research was announced July 7 by chairman of the board of trustees, Dr. Karl A. Meyer. An initial $5,000 contribution has been made by the institute and will be supplemented by friends. The fund will be used for research in immunology.

Fellowship Available.—The Jessie Horton Koessler Fellowship of the Institute of Medicine of Chicago, for the aid of research in biochemistry, physiology, bacteriology, or pathology, will be available on Nov. 1. The stipend is $500 a year with the possibility of renewal for one or two years. Only such applications will be considered as are approved by the head of a department in the fields mentioned or by the director of a research institute or laboratory in Chicago, and which stipulate that the recipient of the fellowship shall be given adequate facilities for carrying out the proposed research. Applications should be sent up to Sept. 1 in quadruplicate to Dr. Paul R. Cannon, Chairman, Committee on the Jessie Horton Koessler Fund, 950 East 59th St., Chicago 37. Application should be made by letter.

INDIANA

Summer Conference Programs.—The departments of medicine of Indiana University Medical Center, Indianapolis General Hospital and the Veterans Administration Hospital are sponsoring conference programs during the summer months. They are presented each Friday evening at 8 p. m. in the classroom of the x-ray department of the Medical Center in Indianapolis, with members of the staffs of the three hospitals alternating in presenting the program.

University Inaugurates Quarter System.—The quarter system for senior medical students at Indiana University School of Medicine, Indianapolis, was inaugurated in June with about one-fourth of the class remaining on the campus during the summer months. Each senior elects the three quarters which he attends and during the fourth quarter is free to take special work or to accept income-producing employment. The plan, enthusiastically accepted by the students, also meets the teaching problem resulting from the large classes in limited classroom, laboratory, and clinic facilities.

IOWA

Dr. Tidrick to Head Surgery Department.—Dr. Robert T. Tidrick, professor of surgery at the State University of Iowa College of Medicine, Iowa City, since 1949, has been appointed chairman of the department effective Sept. 1, succeeding Dr. Nathan A. Womack, who retired recently. Dr. Tidrick has been on the staff of the college of medicine since 1938, successively as assistant resident in surgery, instructor in orthopedic pathology, assistant instructor in surgery, and as assistant, associate, and full-time professor of surgery.

MASSACHUSETTS

Dr. Hawn Succeeds Dr. Wolbach at Harvard.—Dr. Clinton Van Zandt Hawn of Cooperstown, N. Y., has been appointed associate professor of pathology in the Harvard Medical School and pathologist-in-chief of Peter Bent Brigham Hospital, and will assume his new duties in September. Dr. Hawn is now serving as assistant professor of pathology at Columbia University College of Physicians and Surgeons, as pathologist to the Mary Imogene Bassett Hospital in Cooperstown, N. Y., and as director of the Otsego County Laboratories. The pathology department of the Peter Bent Brigham Hospital was created in 1913 by Dr. William T. Councilman, then Shattuck Professor at the Harvard Medical School, and Dr. Wolbach became its head in 1916. Since Dr. Wolbach's retirement in 1947, the department has been conducted by acting heads. As Dr. Wolbach's successor, Dr. Hawn will be the third Harvard scientist to serve as pathologist-in-chief of the Peter Bent Brigham Hospital.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

NEW JERSEY

Dr. Kendall Goes to Princeton.—Dr. Edward C. Kendall, emeritus professor at the Mayo Foundation in Rochester, Minn., has been appointed visiting professor of chemistry at Princeton University. Dr. Kendall was a joint recipient with Dr. Philip S. Hench of the Nobel Prize in 1950 for a program of research leading to the development of cortisone. He will join the staff of the James Forrestal Research Center, bringing with him a program aimed at clarifying the nature of the adrenal cortex.

Personals.—Dr. Hyman I. Goldstein, Camden, has been elected life-time medical historian of the New Jersey Gastroenterological Society. He is an honorary member of the gastroenterological societies of Italy and Belgium, and a correspondent member of the Cuban Society of Cancerology.——Dr. James M. Carlisle, medical director of Merck & Co., Inc., Rahway, since 1936, was awarded an honorary degree of doctor of laws in Dublin by the National University of Ireland.

NEVADA

Reno Surgical Society.—This society will hold its annual meeting August 23-25. The following speakers who will address the society on two different occasions are as follows:

John J. Davies, Baltimore, Use of Metals and Metalic Prosthesis in Surgery; Combined Anterior and Posterior Denervation.
Emile F. Holman, San Francisco, Surgical Experiences with Mediastinal Tumors; Surgical Experiences with the Operative Treatment of Portal Hypertension for the Relief of Hemorrhage and Ascites.
Francis L. Lederer, Chicago, Otolaryngology Today and Tomorrow; Misconceptions: Vertigo, Deafness and the Discharging Ear.
James B. McNaught, Denver, Pathology of the Breast; Pathology of Pulmonary Lesions.
Willis J. Potts, Chicago, Congenital Lesions of the Gastrointestinal Tract; Congenital Lesions of the Chest.
Juan A. del Regato, Colorado Springs, Colo., Radiological Treatment of Carcinoma of the Breast; Treatment of Carcinoma of the Lower Lip.
Herbert F. Traut, San Francisco, Advancements in Gynecology; Mechanisms of Endometrial Bleeding and Their Clinical Significance.

NEW YORK

Personal.—Dr. Henry W. Kaessler, Mount Vernon, is a district governor of Rotary International, world-wide service club organization, for 1951-1952. As governor he coordinates activities of the 56 Rotary Clubs in Bermuda and parts of New York which comprise the 257th Rotary District.

Conference on the Nucleus.—A conference entitled "The Chemistry and Physiology of the Nucleus" will be held at Brookhaven National Laboratory, Upton, Long Island, August 15-17. The conference will feature 18 speakers and five demonstrations. Each speech will be followed by a period for free discussion. Inquiries for reservations should be addressed to Biology Department, Brookhaven National Laboratory, Upton, L. I.

Pritchard Pavilion.—The medical-surgical building at St. Lawrence State Hospital, Ogdensburg, was named the Pritchard Pavilion and dedicated June 13 as a tribute to Dr. John A. Pritchard. Dr. Pritchard retired Jan. 1, 1950, after serving the state for almost half a century. He has been on the staffs of the Brooklyn, Willard, Kings Park, and Buffalo state hospitals. A memorial tablet was unveiled at the pavilion by his fellow workers.

New York City

Medical College Appointment.—Dr. Charles L. Fox Jr. has been appointed research associate in surgery with professorial rank at New York Medical College, Flower and Fifth Avenue Hospitals. Dr. Fox and Dr. James M. Winfield, professor of surgery at the institution, recently received a grant from the United States Public Health Service to support their research on electrolyte metabolism and for the study of improved methods of treating shock caused by burns and other trauma. New research laboratories have been built at New York Medical College, Flower and Fifth Avenue Hospitals for this work. Dr. Fox has been assistant professor of bacteriology at the Columbia University College of Physicians and Surgeons. In addition to his research work at the college, he will assist in teaching basic sciences.

TEXAS

Conference on Animal Diseases.—The Texas State Department of Health, the University of Texas, and Texas Agricultural and Mechanical College sponsored a conference on animal diseases transmissible to man in Austin, Texas, June 12-14. Over 175 were in attendance, including representatives from eight states and Hawaii. Topics discussed included rabies, encephalitis, poliomyelitis, Newcastle disease, conjunctivitis, ornithosis, histoplasmosis, coccidioidomycosis, anthrax, brucellosis, plague, typhus, Bullis fever, leptospirosis, protozoal and spirochetal diseases transmissible to man, Q fever, ringworm infections, and defense against biological warfare. The conference was so successful that plans are being made to make it an annual affair.

WEST VIRGINIA

Morgantown Selected for State Medical School.—An 80-acre tract of land adjacent to the Monongalia General Hospital near Morgantown has been selected by the board of governors of West Virginia University as the site of the new four-year school of medicine, dentistry, and nursing. The tract, donated by the Monongalia County Court, was formally accepted by the board at a meeting July 12 in Morgantown. It was indicated after the meeting that the first unit to be constructed would probably be a classroom building to cost about 2 million dollars. The Court also offered to convey to the board of governors without consideration the Monongalia County General Hospital and Nursing Home, but action on the acceptance of the offer was reserved by the board for future deliberation. In naming Morgantown as the location for the new school, Gov. Okey L. Patteson issued a 33-page statement setting forth his reasons for the selection of Morgantown as the site instead of placing the school at Huntington or Charleston. It is probable that arrangement with the Medical College of Virginia at Richmond for the acceptance of 20 of the 30 graduates each year from the two-year school at Morgantown will be continued until the opening of the four-year school. This arrangement, made several years ago, has worked satisfactorily assuring acceptance annually of two-thirds of the graduating class at West Virginia University's two-year school.

WISCONSIN

Community Honors Physician.—Over 3,000 friends attended the community celebration in Randolph June 16 honoring Dr. Arthur W. Jones, who had served the town for 50 years. The celebration included a parade of floats depicting phases of Dr. Jones' career.

Personal.—Dr. Gerard A. Fostvedt, Barron, gave an address entitled "Extemporaneous Prescription Writing Is Self Taught," before the joint Fifth District meeting of the National Association of Boards of Pharmacy and the American Association of Colleges of Pharmacy, held June 25-26 at Rapid City, S. D.

GENERAL

Study of Medical Care Plans.—The Health Information Foundation is undertaking a two-year study of methods of payment for medical and other health care. The analysis, the foundation says, "will bring out the advantages and shortcomings of various plans, and point the way toward further progress." A grant of $92,000 has been made to Columbia University to make the study.

Photographic Association Meeting.—The annual meeting of the Biological Photographic Association will be held Sept. 12-14 at the Hotel Kenmore, Boston. Typical subjects to be presented include: Improvements in Presentation of Material With Lantern Slides; Aids in Selecting Fields in Photomicrography; Successful Motion Pictures with Limited Equipment; and Photography of the Ocular Fundi. The annual salon, consisting of black-and-white and color prints, color transparencies and motion picture films, will be on exhibit. General chairman of the meeting is F. R. Harding, Children's Medical Center, 300 Longwood Ave., Boston 15.

Heart Association Research Applications.—The American Heart Association is accepting new research applications in cardiovascular and related fields for studies to be conducted during the academic year beginning in July, 1952. Applications for research fellowships and established investigatorships, two categories in which awards are made to individuals, may be submitted up to Sept. 15 of this year. Applications for research grants-in-aid to institutions, including grants for work in the basic sciences, may be filed up to Dec. 1. Information and forms may be obtained from the Medical Director, American Heart Association, 1775 Broadway, New York 19.

Society Elections.—At the annual meeting of the American College of Chest Physicians in Atlantic City, N. J., June 7-10 the following were among the officers elected for the coming year: Dr. Chevalier L. Jackson, Philadelphia, president; Dr. Andrew L. Banyai, Milwaukee, president-elect; Dr. Minas Joannides, Chicago, treasurer, and Dr. Charles K. Petter, Waukegan, Ill., assistant treasurer.——The officers of the New England Dermatological Society for the year 1951-1952 include Dr. G. Marshall Crawford, Brookline, Mass., president; Dr. Maurice J. Strauss, New Haven, Conn., vice president; Dr. Joseph Goodman, Boston, secretary, and Dr. Mildred L. Ryan, Brockton, Mass., treasurer.

National Medical Association Meeting.—The annual convention of the National Medical Association will be held in Philadelphia Aug. 20-24 with headquarters at the Philadelphia Municipal Auditorium and Convention Hall. Dr. Harold H. Walker, Nashville, Tenn., will give the president's address Tuesday at 9 a. m. He will be followed by Dr. Elmer L. Henderson, Louisville, Ky., Past President of the American Medical Association. The concluding speaker will be Dr. Michael O'Heeron, Baylor University College of Medicine, Houston, Texas, who will speak on "Postgraduate Training in the Small Hospital." The rest of the program is organized into section meetings. The Woman's Auxiliary will meet in conjunction with the association.

Scholarships in Cerebral Palsy.—A grant of $10,000 to continue a nationwide educational program for specialists in cerebral palsy has been made by Alpha Chi Omega, women's fraternity, to the National Society for Crippled Children and Adults, Chicago. The grant will make possible advanced study in the care and treatment of cerebral palsied children by specially selected physicians, therapists, and educators during the next two years. It brings to $35,000 the grants made by Alpha Chi Omega to the national society for training on the national level. In addition, $55,000 has been given for scholarships and training on the local level. Thus far, scholarship winners have been selected from 36 states, Hawaii, Canada, and Denmark. Since the beginning of the project, 54 physicians, therapists, and educators have received special training as a result of the Alpha Chi Omega grants.

Radiological Conference.—The Midsummer Radiological Conference of the Rocky Mountain Radiological Society will be held at the Shirley-Savoy Hotel, Denver, Aug. 9-11. Guest speakers who will address the sessions more than once include:

Robert R. Newell, San Francisco, Vision by X-Ray.
Howard P. Doub, Detroit, Cysts of the Mediastinum.
Paul C. Aebersold, Ph.D., Oak Ridge, Tenn., The United States Atomic Energy Program.
Frederick S. Webster, Lincoln, Neb., Growth Changes of the Extremity Associated with Tuberculosis of the Hip.
Hugh F. Hare, Boston, Intracranial Lesions which are Benefited by Radiation Treatment.

There will be a joint meeting with the Denver County Medical Society Thursday evening at 8 p. m. Dr. Hare will speak on "Lymphoid Tumors: A Ten to Twenty-year Follow-up," and Dr. Newell on "Medical Education in Japan." A symposium on "Double Contrast Study of the Colon" is scheduled for Friday evening under the chairmanship of Dr. Robert D. Moreton, Ft. Worth, Texas. Participants will be Drs. John T. Hartman, Harlingen, Texas; Charles W. Yates, Rosenberg, Texas; H. Milton Berg and John R. Williams, Bismarck, N. D.; and Dr. Moreton. The discussion will be opened by Dr. Stuart A. Patterson, Ft. Collins, Colo.

Dr. Gear Appointed Assistant Director General of WHO.—Retirement early next year of Sir Sahib Singh Sokhey of India as assistant director-general of the World Health Organization in charge of the Central Technical Services has brought about the appointment of Dr. Harry Sutherland Gear, deputy chief health officer of the Union of South Africa, to succeed him. Dr. Sokhey's retirement, which is due to his reaching the age limit, will not take effect until next April. However, to insure continuity in the work of the Department of Central Technical Services, Dr. Gear will join the WHO staff in September. From 1932 to 1935 Dr. Gear was in charge of the department of preventive medicine and medical statistics at the Lester Institute in Shanghai. From 1935 until the present he has been on the staff of the health department of the Union of South Africa, except from 1940 to 1944, when he served as senior medical officer with the South African British Armed Forces. In 1946 he was the delegate of the Union to the International Health Conference in New York, at which the creation of WHO was agreed upon. Later he represented his country at the First and Second World Health Assemblies. More recently he served as chairman of the WHO Executive Board for a one-year term. He also served as the board's representative at the Third and Fourth World Health Assemblies.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States in the weeks ended as indicated:

MEETINGS

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, The Homestead, Hot Springs, Va., Sept. 6-8. Dr. William F. Mengert, 2211 Oak Lawn Ave., Dallas, Texas, Secretary.

American Congress of Physical Medicine, Shirley-Savoy Hotel, Denver, Sept. 4-8. Dr. Walter J. Zeiter, 2020 E. 93d St., Cleveland 6, Executive Director.

American Hospital Association, St. Louis, Sept. 17-20. Mr. George Bugbee, 18 E. Division St., Chicago 10, Executive Director.

Colorado State Medical Society, Denver, Sept. 18-21. Mr. Harvey T. Sethman, 1612 Tremont Place, Denver 2, Executive Secretary.

Mississippi Valley Medical Society, Peoria, Ill., Sept. 19-21. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

Montana Medical Association, Great Falls, Sept. 13-16. Mr. L. R. Hegland, 104 N. Broadway, Billings, Executive Secretary.

National Medical Association, Philadelphia, Aug. 20-24. Dr. John T. Givens, 1108 Church St., Norfolk 10, Va., General Secretary.

Neurosurgical Society of America, Sun Valley, Idaho, Sept. 12-14. Dr. C. D. Hawkes, 22 N. Manassas St., Memphis 5, Tenn., Secretary.

Nevada State Medical Association, Riverside Hotel, Reno, Sept. 13-15. Dr. Wesley W. Hall, 307 W. Sixth St., Reno, Secretary.

Northeastern Section, Southeastern Surgical Congress, Lord Baltimore Hotel, Baltimore, Sept. 13-15. Dr. W. Raymond McKenzie, Medical Arts Bldg., Baltimore 1, Secretary.

North Texas-Southern Oklahoma Fall Clinical Conference, Wichita Falls, Texas, Sept. 19. Dr. W. L. Powers, 517 Hamilton Bldg., Wichita Falls, Chairman.

Pennsylvania, Medical Society of the State of, Pittsburgh, Sept. 16-20. Dr. Walter F. Donaldson, 500 Penn Ave., Pittsburgh 22, Secretary.

Reno Surgical Society Conference, Riverside Hotel, Reno, Nev., Aug. 23-25. Dr. Olin C. Moulton, 130 N. Virginia St., Reno, Nev., Chairman.

Rocky Mountain Radiological Society, Denver, Aug. 9-11. Dr. Maurice D. Frazer, 1037 Stuart Building, Lincoln, Nebr., Secretary.

Texas Academy of General Practice, Shamrock Hotel, Houston, Texas, Sept. 10-11. Dr. B. H. Bayer, 104 E. 20th St., Houston 8, Secretary.

U. S. Chapter, International College of Surgeons, Palmer House, Chicago, Sept. 10-14. Dr. Arnold S. Jackson, 1516 Lake Shore Drive, Chicago, Executive Secretary.

Utah State Medical Association, Salt Lake City, Sept. 13-15. Dr. T. C. Weggeland, 42 S. Fifth East St., Salt Lake City, Secretary.

Washington State Medical Association, Olympic Hotel, Seattle, Sept. 9-12. Dr. James W. Haviland, 338 White-Henry-Stuart Bldg., Seattle, Secretary.

Western Society of Electro-Encephalography, Olympic Hotel, Seattle, Sept. 7-9. Dr. Nicholas A. Bercel, 450 N. Bedford Drive, Beverly Hills, Calif., Secretary.

INTERNATIONAL

European Congress on Rheumatism, Barcelona, Spain, Sept. 24-27. Dr. Gunnar Edström, Sweden, Secretary.

General Practitioners Study Club International, Rome, Italy, Sept. 12-15. Dr. John O'Connell, 10300 Lackland Road, St. Louis 14, Mo., U. S. A., President.

International Anesthesia Research Society, London, England, Sept. 3-7. Mr. R. W. Cope, University College Hospital, London W.C.1, England.

International Association of Allergists, Zurich, Switzerland, Sept. 23-29. Prof. A. S. Grumbach, Hygiene Institut der Universitaet Zurich, Gloriastr. 32, Zurich, Switzerland.

International Congress of Anesthesiology, Nursing School of the Salpiettre, 47 Boul de l'Hospital, Paris, France, Sept. 20-22. 12 rue de Seine, Paris 6ᵉ, France, Secretariat.

International Congress on Entomology, Amsterdam, Holland, Aug. 17-24. Dr. J. de Wilde, 136 Rapenburgerstraat, Amsterdam, Secretary.

International Congress on Industrial Medicine, Instituto Superior Técnico, Lisbon, Portugal, Sept. 9-15. Dr. Luis Guerreiro, Instituto Nacional do Trabalho e Previdência, Praça do Comercio, Lisbon, Secretary General.

International Congress on Mental Health, Mexico City, Mexico, Dec. 11-19. Mrs. Grace E. O'Neill, Division of World Affairs, National Association on Mental Health, 1790 Broadway, New York 19, N. Y.

International Congress of Physical Medicine, London, England, July 14-19. Dr. A. C. Boyle, 45, Lincoln's Inn Fields, London, W.C.2, England, Honorary Secretary.

International Gerontological Congress, Hotel Jefferson, St. Louis, Mo., U. S. A., Sept. 9-14. Dr. John E. Kirk, 5600 Arsenal Street, St. Louis 9, Mo., Chairman, Program Committee.

International Poliomyelitis Congress, Copenhagen, Denmark, Sept. 3-7. Prof. Dr. Niels Bohr, Statens Seruminstitut, 80 Amager Blvd., Copenhagen S., Denmark, President.

International Society of Surgery, Paris, France, Sept. 24-29. Dr. L. Dejardin, 141, rue Belliard, Brussels, Belgium, Secretary General.

International Society for the Welfare of Cripples, Fifth World Congress, Stockholm, Sweden, Sept. 9-14. Mr. Donald V. Wilson, 54 E. 64th St., New York 21, N. Y., U. S. A., Executive Director.

Pan Pacific Surgical Association Congress, Honolulu, Hawaii, Nov. 7-19. Dr. Forrest J. Pinkerton, Suite 7, Young Bldg., Honolulu, Hawaii, President.

World Confederation for Physical Therapy, Copenhagen, Denmark, Sept. 7-8.

World Medical Association, Stockholm, Sweden, Sept. 15-21. Dr. Louis H. Bauer, 2 E. 103d St., New York 29, N. Y., U. S. A., Secretary General.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 24-26, 1952. Sec., Dr. D. G. Gill, 537 Dexter Ave., Montgomery 4.

Arkansas:* *Regular.* Little Rock, Nov. 8-9. Sec., Dr. Joe Verser, Harrisburg.

California: *Written.* San Francisco, Aug. 20-23. *Oral.* Los Angeles, August 18. *Oral and Clinical Examination for Foreign Medical School Graduates.* Los Angeles, August 19. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento 14.

Colorado:* *Reciprocity.* Denver, Oct. 9. Final date for filing application is Sept. 24. Ex. Sec., Mrs. Beulah H. Hudgens, 831 Republic Bldg., Denver 2.

Georgia: Atlanta, June. August, Oct. 9-11. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

Guam: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Ex. Sec., Dr. John Y. Battenfield, Agana.

Illinois: Chicago, Oct. 9-11. Superintendent of Registration, Mr. Charles F. Kervin; Capitol Building, Springfield.

Indiana: Indianapolis, June 1952. Sec., Dr. Paul R. Tindall, 1138 K of P Bldg., Indianapolis 4.

Kansas: Topeka, Dec. 12-13. Sec., Dr. O. W. Davidson, 772 New Brotherhood Bldg., Kansas City.

Kentucky: *Examination.* Louisville, Dec. 11-13. Sec., Dr. Bruce Underwood, 620 S. 3rd St., Louisville.

Maryland: *Examination.* Baltimore, Dec. 11-14. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore.

Michigan:* *Examination.* Lansing, Oct. 10-12. Sec., Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing.

Minnesota: * Minneapolis, Oct. 16-18. Sec., Dr. Julian F. DuBois, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Reciprocity.* Jackson, December. Asst. Sec., Dr. R. N. Whitfield, Old Capitol Bldg., Jackson.

Nevada:* Carson City, August 6. Sec., Dr. G. H. Ross, 112 North Curry St., Carson City.

New Hampshire: Concord, Sept. 12-13. Sec., Dr. John Samuel Wheeler, Room 107 State House, Concord.

New Jersey: *Examination.* Trenton, Oct. 16-19. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New Mexico:* Santa Fe, Oct. 8-9. Sec., Dr. Charles J. McGoey, Coronado Bldg., Santa Fe.

New York: *Examination.* Albany, Buffalo, New York and Syracuse, Oct. 31-Nov. 3. Sec., Dr. Jacob L. Lochner, Jr., 23 S. Pearl St., Albany.

Ohio: *Examination.* Columbus, December. *Reciprocity.* Columbus, Aug. 14 and Oct. 2. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

Puerto Rico: *Examination.* Santurce, Sept. 4. Sec., Mr. Luis Cueto Coll, Box 3717, Santurce.

South Carolina: *Reciprocity.* Columbia, Aug. 6, Sept. 10, Oct. 1. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

Texas: * *Reciprocity.* Marlin, Aug. 5. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Ft. Worth.

Virgin Islands: Charlotte Amlie, Nov. 7-8. Sec., Dr. Earle M. Rice, St. Thomas.

Wyoming: *Examination.* Cheyenne, Oct. 1. Sec., Dr. Franklin D. Yoder, State Capitol, Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: Juneau, August. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

Arizona: *Examination.* Tucson, Sept. 18. Sec., Mr. Francis A. Roy, 423 Liberal Arts Bldg., University of Arizona, Tucson.

District of Columbia: *Examination.* Washington, Oct. 22-23. Sec., Dr. *Daniel L. Seckinger, 4130 E. Municipal Bldg., Washington.*

Michigan: Detroit and Ann Arbor, Oct. 12-13. *Examination.* Sec., Miss Eloise LeBeau, 501 W. Michigan Ave., Lansing 15.

Minnesota: *Examination.* Minneapolis, Oct. 2-3. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis.

Nebraska: *Examination.* Omaha, Oct. 2-3. Director, Bureau of Examining Boards, Mr. Oscar F. Humble, Room 1009, State Capitol Bldg., Lincoln 9.

Nevada: *Examination.* Reno, July 3. Sec., Mr. Frank Richardson, University of Nevada, Reno.

Oklahoma: Oklahoma City, Sept. 14. Sec., Dr. Frank C. Gallaher, 813 Braniff Bldg., Oklahoma City 4.

Oregon: *Examination.* Portland, Sept. 8 and Dec. 1. Sec., Dr. Charles D. Byrne, State Board of Higher Education, University of Oregon, Eugene.

Rhode Island: *Examination.* Providence, August 8. Administrator of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

Texas: *Examination.* Austin, October. Chief Clerk, Mr. B. H. Kirk, 306 Nalle Bldg., Austin.

Wisconsin: *Examination.* Madison, Sept. 22. Sec., Mr. W. H. Barber, Ripon College, Ripon.

---

* Basic Science Certificate required.

DEATHS

Dock, George ⊕ recipient of the Distinguished Service Medal and Award of the American Medical Association in 1944, died at his home in Altadena, Calif., May 30, at the age of 91, of pneumonia. Dr. Dock was born at Hopewell, Pa., April 1, 1860. He received the doctor of medicine degree of the University of Pennsylvania Department of Medicine, Philadelphia, in 1884. From 1887 to 1888 Dr. Dock was an assistant in clinical pathology at the University of Pennsylvania, becoming professor of pathology at the Texas Medical College and Hospital, Galveston, in 1888. He left Texas in 1891, to become professor of theory and practice of medicine and clinical medicine at the University of Michigan, Ann Arbor, where he remained until 1908. From 1908 until 1910 he held the title of professor of theory and practice of medicine at Tulane University of Louisiana School of Medicine in New Orleans. He was professor of medicine and dean at Washington University School of Medicine in St. Louis from 1910 to 1922. At the time of his death he was an honorary professor of medicine at the University of Southern California in Los Angeles. Dr. Dock was a member of numerous scientific societies, including the American Association for the Advancement of Science and the Association of American Physicians, of which he had been president in 1916-1917; a fellow of the American College of Physicians, and an honorary member of the Los Angeles County Medical Society. In 1897 and in 1913 he was vice president of the International Medical Congress, at Moscow and London, respectively. A member of the American Medical Association, Dr. Dock served in the House of Delegates in 1908-1909. Previous to 1934 he was for a number of years president of the Barlow Medical Library Association. Since 1934, when that library became the library of the Los Angeles County Medical Association, he had served on the library committee of this organization. During the celebration of Dr. Dock's 80th birthday by the Los Angeles County Medical Society in 1940, on which occasion the organization of the Walter Jarvis Barlow Society of the History of Medicine simultaneously held its first public meeting, Dr. Dock gave the first lecture of the George Dock Lectureship in the History of Medicine. He was a specialist certified by the American Board of Internal Medicine, a surgeon during the Spanish-American War and World War I, and the oldest member of the staff of Huntington Memorial Hospital. Dr. Dock was the co-author of a book on hookworm disease and of articles and chapters in many textbooks on medicine and served on the editorial board of *Archives of Internal Medicine*. He was awarded an honorary A.M. degree from Harvard in 1895, the Sc.D. degree from the University of Pennsylvania in 1904, and the LL.D. degree from the University of Southern California in Los Angeles in 1936.

Donohoe, Lucius Francis ⊕ Bayonne, N. J.; born Jan. 6, 1868; University of the City of New York Medical Department, New York, 1889; served as acting president of the Medical Society of New Jersey; past president of the Hudson County Medical Society; formerly mayor, city commissioner, county physician, and president of the board of education; served during World War I and was named a chevalier of the Legion of Honor by the French Republic in recognition of his services in France; fellow of the American College of Surgeons; member of the founders group of the American Board of Surgery; member of the House of Delegates of the American Medical Association from 1939 through 1945 and in 1947; affiliated with Bayonne Hospital since 1894, serving as president of the medical board of the hospital, medical director and vice president of the board of directors; served on the state board of visitors of the Agricultural College of Rutgers University, New Brunswick; died May 23, aged 83, of arteriosclerotic heart disease.

Dunning, William Meddaugh ⊕ New York; born in Branchville, N. J., Dec. 23, 1868; University of the City of New York Medical Department, 1892; an Associate Fellow of the American Medical Association; specialist certified by the American Board of Otolaryngology; past president of the Bronx County Medical Society; served as vice president of the Medical Society of the State of New York; formerly professor of otology at Fordham University School of Medicine and on the faculty of the New York Post-Graduate Medical School; for many years affiliated with the Bronx Eye and Ear Infirmary; for a time consulting surgeon at the Manhattan Eye and Ear Infirmary and consulting otologist at Fordham Hospital, the Ossining (N. Y.) Hospital, and the Alexander Linn Hospital in Sussex, N. J.; in 1912 exhibited prepared specimens of the temporal bone before the International Otological Society in Boston; author of "Submucous Resection of the Nasal Septum"; died May 11, aged 82, of coronary heart disease.

Marrs, Frederick Addison ⊕ Stevens Point, Wis.; Northwestern University Medical School, Chicago, 1912; also a graduate in pharmacy; member of the American Association of Industrial Physicians and Surgeons; past president of the Portage County Medical Society and the Ninth Councilor District Medical Society; formerly physician for the athletic department of Central State Teachers College; for many years city health officer; served as local physician for the Soo Line Railroad; one of the first members of the staff of St. Michael's Hospital; died March 22, aged 68.

Agan, John Newton, Los Angeles; Hospital College of Medicine, Louisville, 1891; died May 17, aged 87, of arteriosclerosis.

Anderson, Earvye Harry ⊕ Chicago; Loyola University School of Medicine, Chicago, 1918; served during World War I; died in Loretto Hospital May 20, aged 63, of acute myocardial infarction and coronary sclerosis.

Bakes, Edwin Clair, Phoenix, Ariz.; University of Louisville (Ky.) Medical Department, 1903; member of the American Medical Association; civilian examiner for the army induction station; affiliated with Good Samaritan Hospital, where he died May 31, aged 72.

Beaudoux, Henry Alexander, Saratoga, Calif.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1895; member of the American Medical Association; specialist certified by the American Board of Ophthalmology; served during World War I; affiliated with O'Conner Hospital in San Jose; died May 20, aged 79, of coronary occlusion.

Becker, Eli George ⊕ Convoy, Ohio; Eclectic Medical Hospital, Cincinnati, 1926; member of the Van Wert County Board of Health; on the staffs of Van Wert County Hospital in Van Wert, Ohio, and the Methodist Hospital in Fort Wayne, Ind., where he died May 19, aged 54, of carcinoma.

Black, Martin Luther, Knoxville, Tenn.; Lincoln Memorial University Medical Department, Knoxville, 1915; member of the American Medical Association; served during World War I; died in Knoxville General Hospital May 31, aged 62, of carcinoma of the lung.

Bossingham, Ottmer Nathaniel, Clarinda, Iowa; State University of Iowa College of Medicine, 1898; member of the American Medical Association; served on the staff of Clarinda Municipal Hospital; died May 28, aged 79, of coronary occlusion.

Brown, Stanley Robert, Elizabeth, N. J.; New York Homeopathic Medical College and Hospital, New York, 1895; died in Hawthorne, N. Y., May 25, aged 79, of coronary occlusion.

Butler, William Lucas ⊕ Stafford, Kan.; University of Tennessee College of Medicine, Memphis, 1912; member of the American Association of Railway Surgeons; for many years surgeon for the Santa Fe Railway; served during World War I; chief of staff, Stafford City Hospital; affiliated with Grace Hospital in Hutchinson; charter member and past president of the Rotary Club; died in St. Elizabeth Mercy Hospital, Hutchinson, May 25, aged 64, of carcinoma of the right lung.

⊕ Indicates Fellow of the American Medical Association.

Casey, Emmet Francis, Chicago; University of Illinois College of Medicine, Chicago, 1916; served during World War II; died in the Veterans Administration Hospital, Hines, May 19, aged 56, of pneumonia.

Chamness, Clyde James, Elkville, Ill.; Chicago College of Medicine and Surgery, 1910; served overseas during World War I; affiliated with Marshall Browning Hospital in DuQuoin; died in St. John's Hospital, St. Louis, May 13, aged 63, of hypertension and cerebral vascular accident.

Cliff, Harry Roberts, Portland, Ore.; Darlington Medical School, Sydney, Australia, 1880; member of the American Medical Association; at one time a medical officer in the Australian Navy; formerly practiced in St. Helens, where he had been mayor; for many years county health officer; from 1914 to 1943 director of Multnomah County Hospital, where he died May 23, aged 91, of cerebral hemorrhage.

Dalberg, Walter James, Elizabeth, N. J.; Albert-Ludwigs-Universität Medizinische Fakultät, Freiburg, Baden, Germany, 1920; member of the American Medical Association; affiliated with St. Elizabeth Hospital in Elizabeth and St. Barnabas Hospital in Newark; died May 14, aged 58, of coronary thrombosis.

Darnell, William Turner, Middletown, Ohio; Jenner Medical College, Chicago, 1908; member of the American Medical Association; served during World War I; on the staff of the Middletown Hospital, where he died May 28, aged 68, of coronary thrombosis.

Demase, Joseph Charles, Pittsburgh; University of Pittsburgh School of Medicine, 1947; served during World War II; teaching fellow in obstetrics and gynecology at Elizabeth Steel Magee Hospital, where he died May 14, aged 27, of acute myocarditis.

Dunn, Oscar Orlando, Bradford, Ark.; University of Arkansas School of Medicine, Little Rock, 1911; died in Newport May 17, aged 66.

Easley, Henry Owen, Iron Gate, Va.; University of Virginia Department of Medicine, Charlottesville, 1904; member of the American Medical Association; served as president of the Alleghany-Bath Counties Medical Society; affiliated with Chesapeake and Ohio Hospital in Clifton Forge, where he died March 25, aged 71, of cerebral hemorrhage.

Eason, William Henry, Tupelo, Miss.; Memphis (Tenn.) Hospital Medical College, 1913; member of the American Medical Association; affiliated with North Mississippi Community Hospital; died May 11, aged 64, of congestive heart failure.

Eddington, Royal Lacey, Lacon, Ill.; Barnes Medical College, St. Louis, 1900; member of the American Medical Association; past president of the Woodford County Medical Society; served as mayor and county coroner; died in the John C. Proctor Hospital, Peoria, May 15, aged 72, of cerebral hemorrhage.

Ely, Nina Maynard, Los Angeles; Hering Medical College, Chicago, 1900; member of the American Medical Association and the Michigan State Medical Society; died May 23, aged 81.

Farber, William Daniel, Allentown, Pa.; Jefferson Medical College of Philadelphia, 1896; died in Allentown General Hospital May 16, aged 83, of arteriosclerotic heart disease.

Fenton, Alfred Archibald. ⊕ Norwood, Mass.; University of Vermont College of Medicine, Burlington, 1908; served during World War I; school physician; for many years member of the staff of Norwood Hospital; died May 5, aged 66.

Finbury, Charles Mysel, Haverhill, Mass.; Harvard Medical School, Boston, 1949; interned at Kings County Hospital; certified by the National Board of Medical Examiners; died in Massachusetts General Hospital, Boston, February 27, aged 27, of abdominal carcinoma.

Gattis, Emmett, Winchester, Tenn.; Chattanooga Medical College, 1901; died March 29, aged 76.

Gellert, Samuel Morse ⊕ Portland, Ore.; University of Oregon Medical School, Portland, 1907; died in St. Vincent's Hospital May 24, aged 67, of uremia.

Glass, Jesse Oscar, Cleveland; St. Louis College of Physicians and Surgeons, 1903; died May 25, aged 73.

Gordon, Homer James, Chicago; Chicago Medical School, 1921; member of the American Medical Association; field officer for the board of health; affiliated with Mount Sinai Hospital, where he died March 31, aged 53, of carcinoma.

Hamill, Claude Emmett ⊕ Parsons, Kan.; Northwestern University Medical School, Chicago, 1909; died April 6, aged 74, of carcinoma of the inguinal gland and nephritis.

Harris, Bryce Wilson ⊕ Memphis, Tenn.; University of Tennessee College of Medicine, Memphis, 1922; member of the Medical Association of Georgia; at one time served in the regular U. S. Navy; died April 12, aged 57, of coronary thrombosis.

Hayhurst, Leman Harrison, Greenwich, Ohio; University of Louisville (Ky.) Medical Department, 1910; served for several terms on the board of education and as president for one term; affiliated with Willard Municipal Hospital in Willard, where he died May 16, aged 75, of carcinoma of the pancreas.

Hill, William Isaac, Albemarle, N. C.; University of Maryland School of Medicine, Baltimore, 1897; member of the American Medical Association; county health officer; affiliated with Stanly County Hospital; died May 23, aged 81, of coronary occlusion.

Hutchinson, Joseph L. ⊕ Seattle; Milwaukee Medical College, 1905; an Associate Fellow of the American Medical Association; affiliated with Providence Hospital; died May 20, aged 78, of cerebral thrombosis.

Jones, William Monroe, Tulsa, Okla.; John A. Creighton Medical College, Omaha, 1905; member of the American Medical Association; died May 21, aged 76.

Kelley, Erwin E., Herkimer, N. Y.; the Hahnemann Medical College and Hospital, Chicago, 1886; formerly assemblyman for New York State; died May 27, aged 88, of cerebral embolism and terminal pneumonia.

Kerr, Frederick William Jr., Staten Island, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1926; member of the American Medical Association; affiliated with St. Vincent's, Staten Island, Sea View, and Richmond Memorial hospitals; died May 22, aged 50, of heart disease.

Kolipinski, Louis Xavier ⊕ Richmond, Va.; Medical College of Virginia, Richmond, 1936; member of the American Psychiatric Association; served during World War II; died March 31, aged 44, of heart disease.

Krohn, Irwin Kjelland ⊕ Black River Falls, Wis.; Rush Medical College, Chicago, 1924; physician in charge of the Krohn Hospital and Clinic, of which he was a founder; died May 12, aged 51, of coronary occlusion.

Lindquist, Nils S., South Bend, Ind.; the Hahnemann Medical College and Hospital, Chicago, 1899; died in St. Joseph's Hospital April 29, aged 75, of coronary thrombosis.

Loughlin, John Joseph, New York; Fordham University School of Medicine, New York, 1915; member of the American Medical Association; for many years with the police department, serving as its chief surgeon; died May 26, aged 62.

Lyon, Herbert Millard ⊕ Buffalo; University of Buffalo School of Medicine, 1929; president of the board of trustees of Taylor University, Upland, Ind.; affiliated with Deaconess Hospital; died in Sisters of Charity Hospital May 24, aged 48.

McGuire, Evaline Merriam, Humeston, Iowa; Woman's Medical College, Chicago, 1891; died in Garden Grove, April 28, aged 85, of myocardial failure and cardiovascular renal disease.

Martin, Leon Herbert, Okeechobee, Fla.; Barnes Medical College, St. Louis, 1910; member of the American Medical Association; served overseas during World War I and was awarded the Silver Star; served during World War II; died in the U. S. Air Force Hospital, Tampa, Fla., May 17, aged 61, of arteriosclerosis and cerebral hemorrhage.

Mitchell, James M., Oblong, Ill.; Hospital College of Medicine, Louisville, 1901; member of the American Medical Association; died March 28, aged 96, of chronic endocarditis.

Smith, Thomas D., Kingsburg, Calif.; Eclectic Medical Institute, Cincinnati, 1892; affiliated with Selma Sanitarium in Selma, where he died May 15, aged 86, of chronic myocarditis.

GOVERNMENT SERVICES

ARMY

Army Needs Women Medical Specialists.—The Army has renewed its call for more women medical specialists, and has reduced the minimum tour of active duty from the 21 months to 12 months, with opportunities for appointment in the Regular Army.

Last January the Army indicated a need for 247 dieticians, 179 physical therapists, and 146 occupational therapists, but only 22 dieticians, six physical therapists, and 19 occupational therapists were obtained and ordered to active military service by May of this year.

To simplify the procurement of these specialists, procurement officers have been made available in Army Area Headquarters to conduct personal interviews and acquaint qualified women specialists with opportunities available to them in the Army.

Additional information may be obtained from any Army Area Headquarters, or by writing to the Surgeon General, Department of the Army, Washington 25, D. C., attention: Chief, Women's Medical Specialist Corps.

Conference of Professors of Military Medicine.—The sixth annual Army-Air Force Medical Service Conference of professors of military science and tactics will be held August 6-9 at the Medical Field Service School, Ft. Sam Houston, Texas. This conference is held yearly for the 76 Army and Air Force officers assigned as professors of military science and tactics in 48 medical, 18 dental, six veterinary and four pharmacy schools throughout the country. The majority of the 30 newly assigned officers are recently rotated veterans of the Korean campaign.

Among the participants will be representatives of the Adjutant General's Office; the Armed Forces Medical Policy Council; Office of the Chief, Army Field Forces, and the Surgeons General's offices of the Army and Air Force, and liaison officers of the Royal Army Medical Corps and the Royal Canadian Army Medical Corps.

Personal.—Col. Tom F. Whayne (MC) has assumed the duties of chief, preventive medicine division, Office of the Surgeon General, replacing Col. Don Longfellow who has been named a special assistant to the Surgeon General and detailed to the Army Logistical Support Panel at Ft. Monroe, Va.

AIR FORCE

Aerial Hospital Units.—During a two-day conference at the School of Aviation Medicine, Randolph Field, Texas, in July, Brig. Gen. Otis O. Benson Jr., commandant of the school, said that operations in Korea over the past year have shown that it is entirely practical to remove Armed Forces casualties from the fighting fronts by plane. But a continuous research program is necessary to insure the utmost comfort and safety for litter-borne passengers. The Air Force has been given responsibility for evacuating front-line patients for all branches of the Armed Forces, returning them to hospitals in the rear. Materiel needed to carry out this mission includes light planes and helicopters to assemble the wounded in forward areas, airborne medical units, and trained personnel, in addition to the long-range aircraft that fly the casualties home from a war theater.

Maj. Charles A. Cubbler, from the Surgeon General's office, reported that Air Force helicopter squadrons are being organized with all possible speed to take over the work of the miscellaneous airlift facilities improvised by the various arms of the Services as the Korean War expanded. Aerial hospital units have been designed that can be set up anywhere in a combat zone, providing emergency medical treatment at the airhead. The School of Aviation Medicine, in cooperation with the Military Air Transport Service, has worked out standard procedures for handling patients both in flight and on the ground.

Underground Hospital.—On Johnston Island, a unit of barren coral rock that is a strategic base for the Pacific Division of the Military Air Transport Service, there is a modern dispensary-hospital located eight feet under the sandy surface. It is entered through a concrete ramp that turns to baffle the force of possible bomb bursts. An independent auxiliary power plant provides light and electricity for sterilizers and other equipment, and for the blower system. Fourteen patients can normally be taken care of in the ward, but this number can be increased in case of emergency. At present only minor cases are treated at Johnston. Severe cases are flown to Hickam Air Force Base, near Honolulu, 819 miles away. The hospital includes the ward, office, administration section, recreation room, surgery, pharmacy and laboratory, and x-ray room. It is staffed by 14 medical technicians, and is headed by Dr. (Capt.) John T. Martin.

MISCELLANEOUS

Enlarge Radioisotope Export Program.—The U. S. Atomic Energy Commission on July 15 enlarged its radioisotope export program to include all radioactive materials now sold in this country on an unrestricted basis. This action increased the number of United States-produced isotopes available to buyers in foreign countries from 26 to 99.

The U. S. radioisotope export program has been in effect since Sept. 3, 1947, since which time 34 countries have completed arrangements to receive these radioactive substances. The isotopes most in demand in foreign countries have been P^{32}, I^{131}, and C^{14}. P^{32} is useful in agriculture and medicine, notably to determine the most efficient ways of using fertilizer, to locate brain tumors, and as a palliative treatment for certain types of leukemia. I^{131} is useful in medicine, notably in the diagnosis and treatment of thyroid disorders and the treatment of thyroid cancer. C^{14} is useful in a number of different fields, including particularly the study of plant and animal physiology.

The Commission said, in part:

> There is nothing secret or evil about radioisotopes in the forms in which they are sold in this country and abroad. While their utilization cannot significantly advance the atomic energy programs of nations, they can contribute, and are contributing, significantly to advancements in basic science, medicine, agriculture and industry. As of today, isotopes constitute the single most important contribution of atomic energy to peacetime welfare.

The new isotope program also permits the Oak Ridge National Laboratory, which produces most United States radioisotopes, to provide special irradiation services to scientists of other nations. Under this program, foreign scientists may send special materials to Oak Ridge to be made radioactive by exposure to the intense neutron radiation in the nuclear reactor there.

To buy United States-produced isotopes, foreign users must agree (1) to furnish the U. S. Atomic Energy Commission, on request, or at intervals of not more than one year, results of progress obtained with the use of radioisotopes procured from its facilities; and (2) to facilitate exchange of information and visits, relative to work with radioisotopes, between qualified scientists, without regard to nationality, in accordance with normal scientific practice. The procedures which foreign buyers must use in ordering isotopes from the United States, as well as information on the procedures United States buyers must use in ordering isotopes from Canada and the United Kingdom, are described in the 1951 Isotopes Catalog, available from the AEC Isotopes Division, Export-Import Branch, Oak Ridge, Tenn.

Personal.—After 39 years in Federal Food and Drug Law enforcement, Dr. Louis D. Elliott, associate commissioner of food and drugs, retired on June 30, and will be succeeded by Malcolm R. Stephens, now chief of the Chicago District.

FOREIGN LETTERS

PARIS

Diphtheria and Antidiphtheria Vaccination in Paris.—This subject was discussed at a recent meeting of the National Academy of Medicine. In 1925, before widespread vaccination, 2,836 cases of diphtheria, 188 of which were fatal, were recorded. In 1950, when 92% of the school children were vaccinated, 164 cases of diphtheria, of which five were fatal, were recorded in Paris. Four of these deaths occurred in nonvaccinated children. The report stresses that, among the 3,231,578 vaccinations, no serious incident was noted.

Production of Antibiotics in France.—France has begun to export, instead of import, antibiotics. In 1946, the amount of penicillin was 476 billion units; in 1947, imports fell to 251 billion units. Since 1948 there has been no importation, and since March, 1950, the production of penicillin has allowed export of 100 to 500 kg. per month. In 1946, 51 kg. of streptomycin was imported; and in 1949, 12,286 kg.; in 1950, the production of 1,200 to 1,300 kg. per month allowed monthly export of 200 to 300 kg. The same progress has been made with respect to tyrothricin. The national production of aureomycin, however, is in its early stages.

Meeting of the Council of the International Youth Center.—The fifth meeting of the International Youth Center, created in 1949, was held on May 21 and 22 at Longchamp Castle, Paris, under the presidency of Prof. Debré. Those present included Dr. Rajchman, vice president, Professors Aujaleu (Paris), Fanconi (Zurich), Carnero (UNESCO, Brazilian delegate), Guest (Cincinnati), and Wallgreen (Stockholm), and Drs. A. Wauters, past general director of the International Youth Center, and Gaud, general secretary.

The Center contains, in addition to lecture and meeting rooms, a library and reading room, and a BCG pilot station. The construction and arrangement, in the castle park, of a technical center (chemistry, biology, and seroimmunology laboratories) will be completed within a few months. The teaching program for 1951 is varied. It includes a course of social pediatrics from March 5 to June 30, which will be attended by 50 pediatricians, health officers, and social workers of 34 nations (47 have a scholarship from the Center and three from the World Health Organization). In addition to lectures and instruction, trips to Lille, Nancy, Strasbourg, Lyons, Mégève, and Rome will be arranged. There will also be a course on the rehabilitation of children with motor disability, attended by 30 pupils from 18 nations with Center scholarships. From Oct. 15 to Dec. 15, 1951, various methods of immunization and modern techniques of preparation of vaccines against the common contagious diseases of children will be presented to 30 epidemiologists from some 26 nations, 24 with Center scholarships and six with WHO scholarships.

Scientific studies include consideration of an immunological explanation for congenital defects associated with maternal virus disease, such as rubella, and research on antipertussis vaccination. The Center is subsidizing research, undertaken jointly in Paris and London, concerning the effect on the young child of lack of maternal care.

The activities for 1952 were scheduled. In addition to the courses given in 1951, there will be a colloquium on the problems of child welfare in tropical countries held in one of these countries and a seminar on the use of antibiotics in children's diseases. The study on pertussis will be extended to the use of liquid culture mediums for obtaining the vaccine and its intradermal administration. The president transmitted the request of certain countries of Africa and Near East for the Center's help in drives against trachoma and seasonal conjunctivitis and flies, which are the main vectors of these diseases.

Vitamin B_{12} in Herpes Zoster.—In *Le Médecin français* of May, 1951, R. Heyblon published the results of treatment with vitamin B_{12} in 11 cases of herpes zoster. In eight cases, recovery without sequelae was obtained in two to six days. The violent pains were suppressed with an average dose of 20 to 60 micrograms. He proposes the daily administration of 30 micrograms during eight days.

Death of Prof. Leroux.—Prof. Leroux, a member of the National Academy of Medicine, was a prominent anatomopathologist. He was an associate director of the cancer institute for several years. His numerous works were especially concerned with the experimental reproduction of tumors and their curability by physical means. Prof. Leroux was a great master of medical teaching.

SWEDEN

Medical Preparations for War.—In the fall of 1950, representatives of the leading medical societies in Sweden agreed to hold a joint meeting at which the medical profession would be informed of plans for various problems in the event of World War III. This meeting materialized on April 13-14, 1951, and was attended by some 500 doctors and many laymen with important duties arising from totalitarian warfare. At this meeting, lectures were given by experts on one or other of the 12 following items: treatment of shock and burns, blood transfusion, radiological lesions caused by atomic bombs and radioactive weapons, chemical and bacteriological warfare, principles governing surgical treatment, detonation lesions, inanition due to war injuries, infectious diseases under war conditions and mass migration, psychological defense measures and control of panic, and organization of warfare psychiatry.

The organ of the Swedish Medical Association, *Svenska Läkartidningen*, has undertaken to publish these lectures in fortnightly installments. It was stated frankly at this meeting that one of the greatest problems to be tackled concerns the already existing as well as the anticipated shortage of both doctors and nurses. Even the 241 doctors over age 70 will have special duties assigned them. As for the 4,547 doctors under this age, as many as 1,936 will be called on for military service and the remainder for various other services. To economize in doctors, most of them will be attached to hospitals for inpatient and outpatient services. Central hospitals will retain only about 10% of their original patients, two-thirds of whom will be sent home and a quarter transferred to smaller and less exposed hospitals.

There are some 19,000 women who have been trained as nurses, but some 1,500 of them have been pensioned off and some 3,600 have married and have children under the age of 15. These married nurses will, however, be called up, and special arrangements will be made for the care of their children. Some 2,000 midwives will also have to play their part, and many of them will be diverted from their present duties. Preparations for biological warfare require an organization for the rapid limitation of epidemic diseases by isolation, vaccination, and other measures which may be linked up with regional laboratories still in their infancy. Provision is also being made for vaccination on a large scale against tetanus in the fighting forces. The wholesale adaptation of motor buses to the transport of the sick is also being organized.

The Bright Side of Hospital Administration Today.—A recent study of conditions in the central hospital of the County of Stockholm has encouraged Dr. Bertil Bager of Stocksund to challenge the present tendency to bemoan the difficulties due to the shortage of hospital workers, the high cost of living, overcrowding, and obstacles in the way of modernizing old and building new hospitals. He suggests looking on the bright side to see

---

The items in these letters are contributed by regular correspondents in the various foreign countries what a marvelous revolution has occurred during the last decade, owing to the efficacy of new drugs, early ambulation after operation, new methods of operation, better anesthesia, more reliable radiological diagnosis, improved laboratory tests, more effective preparation of patients for operations, and better after-care. All these advances in medicine have hastened the turnover of hospital cases with dramatic effect. In the hospital in question, 2,357 patients were admitted in 1940, whereas in 1950 this figure was raised to 4,077 despite the reduction in the number of available beds. During the 11-year period 1940-1950, the length of stay in hospital was reduced from 20.5 to 9.8 days per patient. During the same period the number of operations performed rose from 1,660 in 1940 to 2,754 in 1950.

Another economy in the administration of hospital beds is the evolution of the polyclinic, or outpatient, treatment of some elements of the community who either need not embarrass hospital beds at all or who receive treatment outside hospital in preparation for an operation within its walls. Dr. Bager points out that the average duration of treatment in hospital per head for all the hospitals in Sweden has fallen between 1940 and 1948 from 19 to 15.2 days. Evidently this fall cannot be as great in medical as in surgical hospitals. In a country with an area as large as that of Sweden, conditions with regard to hospital accommodation show great local variation, and the hospital that serves a very wide area with defective means of transportation is bound to keep some patients for a longer time than the hospital not thus handicapped. There is one great drawback to the increased turnover of patients in hospital, particularly a surgical hospital: Much extra nursing care is needed during the first few days after an operation, and, when the operation rate is doubled, the calls made on the nursing staff are also greater.

Congenital Malformation from Rubeola in the Mother.—The widespread epidemics of rubeola throughout Sweden in recent times have drawn attention to the risks of congenital malformation in the offspring of mothers contracting it in the first two or three months of pregnancy. Dr. Rolf Lundström of the State Bacteriological Laboratory in Stockholm has lately pointed out that the laboratory is cooperating with the Swedish Ministry of Health with a view to studying the incidence of such malformations as a sequel to rubeola in early pregnancy. The necessary data are being collected in the maternity centers in the country, and preparations are being made for the histological examination of material obtained in cases of spontaneous abortion presumably due to rubeola. The State Bacteriological Laboratory has prepared a serum from convalescents from rubeola for the treatment of expectant mothers exposed to infection with rubeola during the first four months of pregnancy.

Dr. Lundström deals in the same connection with a wider issue—that of the provision of every member of the community with a health card on which medical data are entered. It would, for example, be an advantage for both doctor and expectant mother to know for certain from such a record whether she had had rubeola. Were this disease to be included among the notifiable diseases, it would be easier to take suitable action when the existence of a previous attack of rubeola is questioned. Soon after the observation by Gregg of Australia in 1941 of the high rate of congenital malformations in children borne to mothers who had suffered from rubeola early in pregnancy, it was feared that the risk of congenital cataract, deaf-mutism, heart disease, microcephaly, mental backwardness and the like might be close to 100% if the infection occurred in the first two months of pregnancy. Dr. Lundström considers this risk much exaggerated, and it may well prove to be under 50%. Yet it is so serious that young girls should be encouraged to contract rubeola and pregnant women should be kept out of contact with it as much as possible. Though rubeola early in pregnancy may sometimes be an indication for interruption of pregnancy, Dr. Lundström urges great caution in taking such action.

Penicillin Prophylaxis for Endemic Scarlatina.—The Slagsta seminary is an institution for the care of mentally defective children and the training of their teachers. It houses, altogether, some 300 persons who during 1948-1950 were the victims of endemic scarlatina and acute infections of the upper respiratory tract. The housing conditions were such that the effective isolation of cases was difficult. In these circumstances various alternatives for combating recurrent outbreaks of scarlatina were discussed, and inoculation with large doses of Dick toxin and prophylactic treatment with sulfonamides were set aside in favor of penicillin. With the cooperation of the State Bacteriological Laboratory and the Stockholm Fever Hospital, Dr. Per Hedlund of Stocksund gave tentative and small doses of penicillin by injection in March, 1949, and by mouth in tablet form in March, 1950. On both occasions a systematic search was made for hemolytic streptococci in the throats and noses of all concerned. In 1949, penicillin was given only to those persons in whom hemolytic streptococci were found. It was given by intramuscular injection (50,000 units dissolved in 1 ml. of isotonic sodium chloride solution) morning and evening for four days. Children under 5 were given half this dose. In 1950, everyone in the seminary was given 50,000 units by mouth morning and evening on an empty stomach for six days.

During this investigation, which lasted about two and a half years, Dr. Hedlund came to the conclusion that with a prophylactic penicillin dosage considerably smaller than the therapeutic dosage, it is possible to combat endemic scarlatina in schools and other institutions with considerable effect. Both in 1949 and in 1950, this treatment effected a considerable reduction in the number of carriers. At the same time new cases of scarlatina did not occur during or directly after this treatment, although a few persons continued to be bacteriologically positive. The nasal mucosa was more effectively rid of hemolytic streptococci than was the throat. Two relatively penicillin-resistant strains of hemolytic streptococci have been isolated at the Stockholm Fever Hospital, but it is most unlikely that they can be responsible for epidemics of scarlatina.

ARGENTINA

First Pan-American Congress of Sports Medicine.—The South American Union of Sports Physicians participated in the organization of the South American congresses in Lima (1939), Buenos Aires (1941), Montevideo (1943), Río de Janeiro (1947), La Paz (1948), and again in Lima (1949). This year, late in February, the First Pan-American Congress of Sports Medicine was held in Buenos Aires at the time of the Pan-American Olympic Games.

The Congress advised the establishment of university chairs of sports medicine for physicians, with a diploma given at the end of the course; also advised were medical examinations before sports activities and organization of research laboratories. It was suggested, too, that women refrain from playing football and from boxing or catching, but basket-ball is acceptable under special rules. The Pan-American Union of Sports was established with Dr. José Pedro Reggi in Buenos Aires as secretary.

Politics in Universities and Hospitals.—The deans of the faculties of all the universities of Argentina "invite" all professors to sign a note asking for the reelection of the Argentine President General Juan Perón, although university law does not allow professors to take part in political activities. Physicians working in hospitals and public administration offices were asked to sign a similar note, in addition to which they must specify the political party to which they belong. Article 4 of the university law reads: "Professors and students should not take part directly or indirectly in politics as members of the university corporation, nor formulate conjoint declarations involving political militancy or intervention in questions alien to their specific function. Those who transgress these dispositions will be subject to suspension or dismissal."

Visitors.—Prof. Charles H. Best visited the scientific centers of Lima (Peru), Santiago (Chile), Córdoba, Rosario, and Buenos Aires (Argentina), Montevideo (Uruguay), and São Paulo and Río de Janeiro (Brazil). He stayed for 29 days in Argentina and delivered 11 interesting lectures. Prof. Best visited laboratories, exchanged ideas, and discussed scientific subjects with Latin American scientists.

Dr. Knoppers, professor of pharmacology in Amsterdam, visited laboratories in Argentina and delivered some lectures.

CORRESPONDENCE

POSTGRADUATE MEDICAL EDUCATION IN MEXICO

To the Editor:—It has been my privilege recently to visit several of the leading medical institutions in Mexico City. The outstanding educational opportunities that are now available in some of these Mexican hospitals should be better known by American physicians.

Among the institutions that are doing excellent research and clinical practice are the Hospital Infantil, the Hospital Nacional de Cardiologia, and the Hospital de Enfermadades de la Nutricion. All of them are affiliated with the national university (Universidad Nacional de Mexico) and offer postgraduate courses of lectures and conferences as well as internships and residencies. Their staffs are distinguished and their directors—Dr. Federico Gomez, Dr. Ignacio Chavez, and Dr. Salvador Zubiran—are internationally known.

In addition to the investigative work conducted at these hospitals, a wide variety of diseases are cared for and all these institutions provide certain clinical advantages. For example, at the Hospital de Enfermadades de la Nutricion there is a great deal of liver and amebic disease of various types; at the Hospital de Cardiologia there is an enormous amount of rheumatic disease much of which is different in character from that seen in the United States; and at the Hospital Infantil one can see patients with typhoid, advanced malnutrition and other disorders which are rarely seen at home. Also, as in Vienna, the autopsy rate is exceedingly high, making it possible to follow through almost all interesting problems.

Besides the institutions mentioned, unusual opportunities exist for work in tuberculosis and in tropical diseases and parasitology. Mexico City itself, as well as the surrounding country, is fascinating and a storehouse of history. In the city proper lies the oldest hospital on the continent still in existence—the Hospital de Jesus, founded and endowed by Cortes. In fact, the list of interesting places and institutions is practically unending.

An English-speaking physician desiring to study in Mexico should have at least a slight knowledge of Spanish beforehand and should plan to concentrate on it further for a while after arrival. This is certainly no more than is done by the many Mexican and other foreign-speaking physicians who study in the United States, and a knowledge of the language, incidentally, carries its own rewards. In some cases North American physicians might be able to obtain junior residencies from the institutions named; the foundations in the United States interested in medical education and the award of fellowships might also look with favor on applications of this kind, since they have always encouraged suitable graduate study abroad.

The possibility of taking some advanced medical training in Mexico is particularly attractive, it seems to me, for physicians planning to enter academic branches of medicine. However, the specialty boards and the Council on Medical Education and Hospitals would doubtless approve appropriately selected study abroad for properly qualified physicians entering the clinical specialties. Those who may be seriously interested in the opportunities that may be available for graduate study of this kind in Mexico can obtain detailed information from the directors of the institutions mentioned.

Edwin P. Jordan, M.D.,
Charlottesville, Va.

Dr. Jordan's letter was referred to the office of the Council on Medical Education and Hospitals, whose comment follows.—Ed.

While Dr. Jordan's comments are of considerable interest, it should be noted that the Council on Medical Education and Hospitals limits its approval for intern and residency training to programs sponsored by hospitals in the United States and its possessions. It is unlikely that the Council's facilities and resources will be expanded sufficiently to enable it to extend its inspection and approval program to other countries. Some examining boards, however, give credit for residency work taken in foreign countries. Physicians interested in training opportunities outside the United States should confirm the acceptance of such training with the secretary of the examining board concerned.

It is possible to utilize the advantages offered in these institutions through the development of affiliating programs by hosptials in this country that have been officially recognized. Residents, under such an arrangement, might rotate for varying periods to the institutions in Mexico, without the latter being independently approved. Credit for training of this nature is granted on the basis of the approval extended to the parent hospital sponsoring the program.

CORTISONE AND ERYTHROCYTE SEDIMENTATION

To the Editor:—The editorial of May 12, 1951, on the effect of cortisone and ACTH on the erythrocyte sedimentation rate placed undue emphasis on but one of the suggested causes for the depression of fibrinogen and gamma globulin during hormonal therapy. Depression of these proteins is not necessarily a primary effect of the hormones, but may be principally a reflection of the effect of the hormones on the inflammatory disease process present in the patients studied.

The stimulus for producing excessive amounts of these proteins, particularly fibrinogen, and thereby effecting an elevation of the sedimentation rate, is usually an inflammatory reaction. This reaction is itself suppressed to a great degree during the period of hormone administration. Several studies, including our own, are summarized in the "Proceedings of the Second Clinical ACTH Conference" and have shown that many of the secondary results of various types of inflammatory reaction, such as fever and antibody production, may be inhibited to some degree by ACTH or cortisone but that this inhibition cannot be divorced from the effects of suppression of the inflammatory reaction itself.

It appears well established by recent careful studies of several investigators that cortisone inhibits the synthesis of certain proteins. This may well be the principal biochemical mechanism by which the hormone inhibits inflammatory responses and experimental wound healing. Although a similar mechanism may operate with respect to the serum proteins mentioned, the preponderant effect in disease states would appear to be inhibition of the inflammatory reaction irrespective of cause.

and Surgeons, New York.

SURGICAL TRAINING

To the Editor:—In regard to the excellent letter of E. P. Lehman in The Journal, May 19, 1951 (page 279), would it not be relevant to express this one truth, that men performing surgical operations should be able to do so safely and well? There is more than one path to any truth. Some men learn best through a residency type of training, others through assistantships. Some men who complete residencies still cannot perform good surgical work. Some residencies give insufficient experience and responsibility, so that such training does not automatically imply excellence.

In the hospital where I work, there are two men carrying on a heavy surgical schedule, one in general surgery, the other in gynecologic surgery, with a very minimal mortality rate. Other general practitioner surgeons with whom I am acquainted perform three and four hundred consecutive major operations without a death.

It is not where a man has been, but what he can do, that counts.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Malpractice: Gauze Dressings in Patient's Throat Following Tonsillectomy.—*The plaintiff sued for damages resulting from the alleged negligence of the defendant in permitting gauze dressing to be left in the tonsil cavity following a tonsillectomy performed on the plaintiff. From a judgment in favor of the plaintiff, the defendant appealed to the Supreme Court of Utah.*

Before discussing the evidence, the Supreme Court pointed out that the better-reasoned cases announce a rule of law to the effect that in those cases which depend upon knowledge of the scientific effect of medicine, the results of surgery, or whether the attending physician exercised the ordinary care, skill and knowledge required of doctors in the community which he serves, must ordinarily be established by the testimony of physicians and surgeons. There is, however, another well-recognized rule holding that when facts may be ascertained by the ordinary use of the senses of lay witnesses, it is not necessary that expert testimony be produced and relied upon. Included within the latter rule, the Supreme Court continued, are those cases which are similar to the present one, namely, those actions involving negligence in leaving instruments, needles, sponges, bandages, gauze or foreign particles in incisions, wounds, or open cavities. So far as establishing negligence on the part of the doctor in this type of case is concerned, it would appear to be a matter of common knowledge that due care is lacking if surgical instruments, sponges, or medical supplies are not removed before an incision is closed or the wound healed; and lack of direct evidence of failure to remove is not fatal to the plaintiff's case when there is evidence from which an inference to that effect may legitimately be drawn.

In July, 1945, the plaintiff engaged the defendant physician to remove her tonsils, which was done under a local anesthetic. The operation consumed about an hour's time and it was necessary for the doctor to use gauze sponges. Immediately following the operation, and for almost three years, the plaintiff had a great deal of difficulty with her throat and she returned many times to the defendant as well as to some twelve other doctors and dentists for treatment during the three-year period. In the latter part of June, 1948, some pieces of cotton thread and gauze were removed from the sores and ulcers in the back of the plaintiff's mouth and from that time on her condition steadily improved.

On the basis of all the evidence, the Supreme Court held that the jury could reasonably find that thread, gauze and possibly catgut had in fact been left in the plaintiff's throat at sometime in the past and was removed therefrom in June, 1948. The question then was as to how the foreign material got into the plaintiff's throat. Three possibilities were suggested: First, that it was left there some twenty-five years before when a number of plaintiff's molars were extracted; second, that it was left there in June, 1946, when eighteen of the plaintiff's front teeth were extracted; third, it was left there by the defendant when he performed the tonsillectomy. The Supreme Court concluded that the jury could reasonably eliminate the first two possibilities. On the basis of the following facts and circumstances, however, the Supreme Court felt that the jury could reasonably find that the materials were left in the plaintiff's throat by the defendant.

Prior to the tonsillectomy plaintiff had not encountered any difficulty with her throat and mouth; the defendant performed the operation after examining her throat and finding only a diseased tonsil. In the course of removing the tonsils, he used gauze sponges to mop the fossa and used catgut to tie the bleeding vessels. He did not see the plaintiff for thirty days and prior to this time scar tissue would have formed and might have covered up any materials left in the tonsil fossa. The depth of the fossa could have been as much as three-quarters of an inch and there must have been considerable bleeding as the large type sponge was used and there was some tieing of blood vessels. Immediately after the operation, plaintiff commenced having difficulty with her throat and continuously for a year and a half thereafter at intervals of from three to four weeks she was returning to defendant's office and complaining about a sore throat and explaining to the defendant or his nurse that it felt like a lump was in her throat. Over a period of three years following the operation, plaintiff consulted with and received advice from twelve doctors or dentists in an attempt to get relief. She requested her remaining teeth to be pulled to remove any possible cause from that source. During that period and prior to the tonsillectomy, no gauze or sponge was inserted in her throat. Members of the medical profession observed the ulcers and concluded plaintiff was suffering from some physical disorder of the throat and mouth and some were of the opinion that cancer might be the cause. Plaintiff consulted experts on that disease and she was referred to Dr. Dolowitz to determine its presence. She submitted to two biopsies for that determination. No one had ever used any sponges, gauze or surgical materials in her mouth besides the defendant and the material exuded from the ulcers came from a sponge similar in type to the one used by the defendant. The defendant used catgut to tie some of the vessels and what appeared to be that type of tieing material was found in the discharge. Four lay witnesses and one medical expert testified to gauze or thread being imbedded in the plaintiff's throat in, around, and about the fossa. The materials exuded or extracted from the ulcerated areas were subjected to scientific analysis and proven to be parts of gauze or sponges. Over the period involved, plaintiff's acts and conduct were entirely consistent with her claim that immediately following the operation a lump developed in her throat, it became sore and continued that way until the foreign materials were removed.

Without question, said the Supreme Court, the evidence supported the verdict in favor of the plaintiff unless the jury was compelled to find that parts of gauze were not left on the fossa but on the ulcers and that the gauze could not have migrated from the fossa to the ulcers. Most of the medical experts testified that the materials could not migrate from the fossa to the area of the ulcers. Dr. Dolowitz, however, said that strange things happen and that it was possible that lateral migration might conceivably take place. Therefore, the jury was not bound to find that such a migration was impossible. This made a question of fact for the jury from which the inference could legitimately be drawn that bits of gauze and thread found in the ulcer were occasioned by leaving a part of a surgical sponge in the tonsil fossa.

The next question, said the Supreme Court, was whether or not the evidence precluded a finding that the gauze or threads could have remained in the tonsil cavity. Unquestionably strings and gauze were embedded in the ulcers and they had to get in the throat in some manner. The jury could, from the evidence, exclude every possibility except that the defendant placed them there. He used gauze material and catgut and it may have been in the use of the latter that the former was held in place. He admitted making an incision and the cut may have been deeper than necessary in a usual operation. In almost every malpractice case of this type there is medical evidence which casts doubt on the cause of the injury, yet the other facts and circumstances may point rather clearly to the cause. This merely results in a conflict in the evidence, to be reconciled by the jury.

In this case the conflict was reconciled by the jury in favor of the plaintiff, and the Supreme Court concluded that the finding of the jury was reasonably supported by the evidence adduced.

Accordingly the judgment in favor of the plaintiff and against the defendant physician was affirmed.—Fredrickson v. Maw, 227 P. (2d) 772 (Utah, 1951).

Retrolental Fibroplasia.—Serial ophthalmoscopic examinations were made on 72 premature infants weighing less than 1,650 gm. at birth. The theory of postnatal development of retrolental fibroplasia was supported by the fact that 56 children showed normal fundi at the initial examination. Sixteen infants showed venous caliber increase and arterial tortuosity of the retinal vessels on the first examination, and three of these infants had preretinal or vitreous hemorrhages. Venous caliber increase and venous and arterial tortuosity were later demonstrated in an additional 28 children. In 34 of the 44 infants these early signs of vascular abnormality were followed by preretinal hemorrhages or by extension of the preretinal hemorrhage into the vitreous. One infant showed hemorrhage without antecedent vessel changes. Retrolental fibroplasia developed in 14 of these 35 infants, and in 13 of them there was a consistent pattern of pathogenesis from the first stage of minimal retinal vessel changes through each of five succeeding stages: preretinal hemorrhage, extension of these hemorrhages into the vitreous, organization of the hemorrhages with angiofibrous proliferation, subsequent retinal detachment, and the formation of a retrolental membrane. The importance of preretinal hemorrhage as a precursor of the succeeding stages of retrolental fibroplasia is stressed. The potential reversibility of the developing retrolental process at any stage short of severe retinal detachment is noted. Sixty-five infants were given *dl*-alpha-tocopherol acetate, 50 mg., three times daily, from birth. In 11, retrolental fibroplasia developed in its partial or complete form, challenging the prophylactic role attributed to the tocopherols in treatment of this disease.

Chloramphenicol Treatment of Typhoid.—In 1949 seven children between the ages of 3 and 6 yr. with typhoid were treated with chloramphenicol (chloromycetin®). In all patients the diagnosis was confirmed by blood and stool cultures and agglutination tests. The disease was severe in three patients, moderately severe in three, and relatively mild in one. The dose of the drug ranged from 0.070 to 0.140 gm. per kilogram of body weight every 24 hours. Therapy was given from 10 to 18 days, with an average of 13.9 days. The in vitro sensitivity of the seven strains of S. typhosa recovered from the patients ranged from 2 to 4 γ (micrograms) of chloramphenicol per cubic centimeter. No relapses and no significant toxic reactions to chloramphenicol were observed. Most patients showed a significant drop in total leukocyte and absolute neutrophil counts during therapy. The leukocyte counts rapidly returned to normal after cessation of treatment.

Interdigital Syphilitic Lesions.—Dexter summarizes 10 cases in which the lesions of secondary syphilis resembled dermatophytosis of the feet. One case is of special interest because the interdigital lesions were dark-field positive and responded to penicillin antisyphilitic therapy first with a localized Herxheimer reaction and then with rapid healing. The interdigital lesions in all the cases epithelized and disappeared rapidly after penicillin therapy without any topical medication. Other skin and mucous membrane lesions of a syphilitic type and a positive serological reaction for syphilis with a high titer are significant observations in the differential diagnosis of interdigital lesions. As yet a dark-field positive lesion has not been observed in a seronegative patient. The course and appearance of the interdigital involvement is somewhat different in syphilis and dermatophytosis. In the latter there has usually been chronic scaling and cracking of the skin on the feet and between the toes preceding the onset of the ulceration. The rare case of epidermophytosis with ulcers as extensive as those found in syphilis is accompanied with more edema, erythema, and induration of the surrounding tissues; cellulitis and lymphangitis usually are present. The ulcers of epidermophytosis are less sharply demarcated, shallower, and more irregular in depth; the appearance is that of spotty superficial erosion. The bases are less red. Evidence of scaling and maceration of adjacent tissue is usually found. Lymphadenopathy, if present, is limited to the inguinal nodes of the involved side in contrast to the more generalized lymph node enlargement usually present in secondary syphilis. Interdigital syphilitic lesions showed no increased seasonal incidence, and the patients with these syphilitic lesions did not have occupations that would cause their feet to be either hot or abnormally moist. Most of the patients said they had had no previous attacks of any but minimal epidermophytosis. In five of the cases fungus cultures were made, all of which were negative.

Coronary Thrombosis Following Shock.—In a series of 3,365 cases of coronary thrombosis there were 40 patients with thrombosis apparently precipitated by shock. Eighteen of these, in whom the thrombosis was proved by autopsy, were studied in detail. All but two were over 50, and all but four showed pathological evidence of previous coronary artery disease. Shock was caused by surgical operation or anesthesia in nine patients, by postoperative peritonitis in two, by barbiturate poisoning in three, and by trauma, burns, insulin, and arsenic poisoning in one each. Shock lasted longer than one hour in the majority of patients. Death occurred from one hour to 12 days after the shock episode, with an average time of 68.8 hr. Thrombosis was thought to result from circulatory stasis and, possibly, sludging of blood in the coronary arteries. Transfusion of adequate quantities of blood or plasma, by increasing the output of blood from the left ventricle and augmenting coronary blood flow, should significantly reduce the tendency to coronary thrombosis and insufficiency in shock. This was not done in the majority of patients in this series. The authors conclude that patients over 50 are susceptible to coronary insufficiency as a result of shock and that in these patients any fall in blood pressure should be avoided if possible. If it does occur, it should be treated vigorously and not allowed to persist for more than a few minutes.

Rheumatoid Arthritis.—The changes induced by corticotrophin (ACTH) in the clinical and laboratory manifestations of rheumatoid arthritis were compared with those occurring during a spontaneous remission in a woman of 21. During both spontaneous and hormone-induced remissions the previous abnormalities in the sedimenation rate, serum proteins, and synovial fluid returned to normal, except that the synovial fluid showed an increased viscosity during corticotrophin administration. Microscopic evidence of a mild synovitis persisted during hormone treatment, as did anemia. Corticotrophin produced prompt but incomplete improvement in all of the clinical manifestations of the disease, but partial or complete withdrawal of the drug was followed by prompt recurrence of both clinical and laboratory manifestations. Hormone therapy was accompanied by many undesirable effects, including acne, hirsutism, moon face, and an acute psychosis.

L. E. Cell.—The diagnostic value of the L. E. cell was confirmed in a study of 22 patients with acute disseminated lupus erythematosus and in a series of patients with diffuse vascular and connective tissue disease. With one exception all the patients with lupus erythematosus showed L. E. cells in bone marrow and peripheral blood. Also with one exception L. E. cells were not found in patients with rheumatoid arthritis, rheumatic fever, dermatomyositis, scleroderma, subacute bacterial endocarditis, blood dyscrasias, lymphoma, or carcinoma. The exception was a patient with amyloidosis of the bone marrow who showed a single L. E. cell that was chemically different from true L. E. cells. The test thus has a sensitivity and a specificity of about 96%. The L. E. cell can be found in clotted blood, so its formation does not depend on the presence of an anticoagulant. The blood must be allowed to stand for at least two minutes after withdrawal from the body before being smeared, and the L. E. cells are most numerous after 20 to 30 min. of incubation. The inclusion body in the L. E. cell is altered nuclear material derived from polymorphonuclear leukocytes and lymphocytes. This material contains partially depolymerized desoxyribose nucleic acid and is identical both optically and chemically with the altered nuclear material found by Klemperer in mesenchymal cells of patients with disseminated lupus erythematosus. The L. E. plasma factor responsible for the production of L. E. cells is found in the gamma globulin fraction of the plasma proteins.

Bromide Intoxication.—The incidence of bromide intoxication continues to be high in spite of numerous warnings to physicians of the hazards of these drugs. Physicians still prescribe bromides without taking adequate precautions against their prolonged use, or patients, unaware of its cumulative toxicity, ignore the advice given. Because of inadequate legislation bromides can be purchased over the counter without a prescription. Symptoms that should suggest the diagnosis are unsteadiness, dizziness, mental confusion, memory loss, and psychotic manifestations in the absence of organic disease. The diagnosis can be easily confirmed by blood bromide determinations. Therapy is simple, and consists of the oral and parenteral administration of large amounts of sodium chloride to hasten the excretion of the bromide ion. Adequate control of this hazard rests with the physician and with legislative bodies.

Experiences with Transorbital Leukotomy. — Seventy-eight female and 32 male patients between 14 and 70 with various mental disorders were subjected to 127 transorbital leukotomies. Seventy-four patients had schizophrenia; 19 had psychoneuroses; 14 had affective psychoses; two had paranoid psychosis, and one had mental deficiency with paranoia. The schizophrenic patients had received the accepted forms of treatment without relief and were considered hopeless, but 39 of them (53%) showed improvement following transorbital leukotomy. Catatonic and paranoid types of schizophrenia responded most favorably in this category, whereas the deteriorating forms showed a low improvement rate. If agitation was a significant feature of the deteriorated type, improvement was obtained after transorbital leukotomy. Among the obsessive-compulsive patients previously subjected to psychotherapeutic techniques and electric convulsive treatment, transorbital leukotomy effected improvement in 16 (84%). Improvement was slow initially but increased with time. The patients with affective psychoses in whom repeated courses of shock therapy had failed to prevent recurrences, particularly those with agitated depressions, responded very favorably to transorbital leukotomy, with five of six manic-depressive patients (83%) and five of eight with involutional depression (63%) improved. Transorbital leukotomy is a comparatively rapid, simple procedure that can be done by a psychiatrist without elaborate equipment or facilities. It has the great advantage over the former methods of lobotomy that it produces no untoward psychological effects. In view of the relative ease of performance, short hospitalization, minimal nursing care, insignificant morbidity, low mortality rate (1.8%), and the favorable results, the authors suggest that this procedure be utilized more widely in suitable cases, so that patients are not unnecessarily relegated to custodial institutions for life or permitted to lead a burdensome existence.

Impaired Cerebral Function in Essential Hypertension.—The effects of relatively early and minimal cerebral damage on the personality patterns and adaptive capacities of 14 patients between 27 and 58 with essential hypertension were studied by combined medical, neurological, experimental psychological, and psychiatric techniques. A psychiatric syndrome characterized by changes in personality patterns, especially in relation to the expression of hostility, the willingness to yield to dependent needs, and reduction in perfectionistic drives, associated with mild judgmental and memory defects, insomnia, loss of energy, and anxiety symptoms that are not explainable by changes in the cardiovascular status, has been observed. The appearance of this syndrome signifies the onset of organic involvement of the brain. The duration of the syndrome depends not so much on the quantitative aspects of the cerebral damage as on the integrative ability of the premorbid personality. Impairment of cerebral function equivalent to that seen in patients with surgical removal of both frontal lobes may occur early in the course of essential hypertension without neurological signs. Neuropathological evidence points to diffuse involvement of the nervous system. The syndrome provides further information regarding the clinical course of hypertension. The mechanisms by which the cerebral damage occurs require further elaboration. The occurrence of symptoms and of alterations in the adaptive capacities in the absence of neurological signs suggests that the changes are biochemical or vasomotor rather than structural.

Peripheral Vascular Disease.—Although crude ergot produces spasm of blood vessels, it also has a latent sympatholytic effect. This effect becomes dominant when the alkaloids of ergot are hydrogenated, and these compounds then become vasodilators. They act centrally by inhibiting the vasomotor center and peripherally by opposing the action of epinephrine. Popkin used the dihydrogenated alkaloids of ergot (dihydroergocornine, dihydroergocristine, and dihydroergokryptine) in an equimixture known as CCK 179 for the treatment of 250 patients with peripheral vascular disease and obstructive edema. This preparation was given parenterally and by mouth in a dose that varied with the response of the patient. Statistically significant improvement was noted in over 60% of the cases followed for approximately two years. Patients with organic occlusive arterial diseases showed the greatest improvement, as evidenced by increased skin temperature, accelerated adaptation to cold, improved healing of ulcers, and decreased rest pain, walking pain, paresthesias, and nocturnal cramps. Vasospastic disorders were rarely benefited. Edema due to thrombophlebitis, posttraumatic causalgia, or venous obstruction was improved. Phantom limb pain was benefited in one case. Toxic or uncomfortable side reactions were rare. More than 25% of the older patients reported an increased sense of well-being while taking this preparation, presumably due to an increase in cerebral circulation, pulmonary ventilation, and skin temperature.

Treatment of Duodenal Ulcer.—Three types of operations were used in 132 cases of duodenal ulcer here reviewed. In 43 cases so-called complete vagotomy was done, with or without supplemental gastroenterostomy; in 47 cases the operation was conventional gastric resection, and in 42 the procedure was hemigastrectomy and so-called subtotal vagotomy, recently described by Stevens. A two year follow-up study revealed that results of gastric resection and hemigastrectomy with subtotal vagotomy were better than results of vagotomy procedures alone. The authors believe that the anticholinergic drug beta-diethylaminoethylxanthene-9-carboxylate methobromide (banthine®) is less effective than vagotomy in the treatment of peptic ulcer. The action of banthine® differs in at least two respects from the result of vagotomy: 1. It reduces total gastric secretion but does not materially decrease titratable acidity. 2. It does not prevent the acid response to insulin hypoglycemia. It has been observed that whereas banthine® bromide is a useful adjunct in the medical treatment of duodenal ulcer, the drug has not materially affected the course of the disease in the type of patient for whom surgery has been indicated heretofore. Although initial reports on the use of this drug in the treatment of peptic ulcer have been encouraging and the results have been compared with those of vagotomy, discrepancies in clinical and laboratory results are already evident. The authors of this report found among patients referred for surgery by internists one case each of recurrent hemorrhage, recurrent intractable pain, and perforation following intensive banthine® therapy.

Treatment of Spontaneous Hemopneumothorax.—The patient with spontaneous hemopneumothorax whose case is reported showed no improvement with routine conservative management. On the third day his dyspnea and orthopnea were severer and x-rays showed increased fluid in his chest. Despite a blood transfusion of 500 cc. the patient seemed to be in borderline shock. Plasma was started, and another chest film and other tests indicated continued bleeding in the left side of the chest. After 1,500 cc. of blood had been removed, an exploratory thoracotomy was done. There was oozing of blood from adhesions in the apex and the left costophrenic angle. The bleeding was controlled by ligatures to the adhesions and by the use of multiple absorbable gelatin sponge (gelfoam®) packs. The postoperative course was smooth. The rapid recovery of this patient is contrasted with the prolonged course of two others who were treated conservatively and who eventually required pulmonary decortication. In a fourth patient conservative therapy also resulted in prolonged hospitalization, and despite subsequent operations this patient died. The authors advise exploratory thoracotomy in cases of massive bleeding not controlled by conservative measures, and they recommend early decortication if conservative procedures have not been successful in producing pulmonary expansion. Thoracotomy was first considered the treatment of choice for almost all cases of hemopneumothorax, but now with streptokinase and streptodornase for prevention of clot formation in the chest, the authors feel that these drugs should be used in connection with the conservative measures. They must be used with caution, however, for if used too early, they may add to the initial bleeding tendency.

Diagnosis of Early Gastric Cancer.—Cancer of the stomach causes more than 25,000 deaths each year in the United States, more than any other type of carcinoma. In discussing gastric cancer, Lawrence gives particular attention to early *diagnosis.* A patient with dyspepsia and in whom gastric cancer is suspected should have a stool examination for occult blood after a three-day period on a meat-free diet, a gastric analysis, and a complete blood cell count. If either the stool is positive for blood or the gastric acidity is abnormally low, then a complete gastrointestinal examination should be made, including gastroscopy and a cytological examination of the gastric contents for malignant cells. Every patient with suspected gastric carcinoma should be operated on, unless distant metastases are demonstrated, and every carcinoma found at operation should be resected if this is technically possible. Gastric polyps are premalignant lesions.

Gastric carcinoma is so frequently associated with pernicious anemia that this also may be considered a premalignant disorder. The prognosis after a successful gastrectomy for early carcinoma is excellent.

Tobacco Smoking and Physical Performance.—Knowledge regarding the effect of tobacco smoking on athletic performance is inadequate. It is possible that there may not be any uniformity in the effect of smoking on different persons, because of several variables, e. g., individual differences, amount of smoke inhaled, speed of smoking, and frequency of smoking. The investigations reported in this paper involve two series of experiments. Thirteen college students were used as subjects, eight of them habitual smokers and five nonsmokers. The subjects performed on a bicycle ergometer a prescribed amount of work, comparable to a one-mile run on the track, in the shortest possible time. Each subject served as his own control, by either smoking or abstaining from smoking. The period of abstinence from smoking was from seven to 10 days. The average riding time for all subjects but one was better when they did not smoke. This, however, was statistically significant for only three smokers and two nonsmokers and was not significant for the group. Abstinence from smoking for one week caused improvement in a tobacco-sensitive subject, and no effect in nonsensitive ones. Reports made by the subjects regarding how they felt before and during the rides had no apparent connection with their performances. Since a relatively large proportion of an athletic team may consist of tobacco-sensitive men, the nonsmoking rule is a wise precaution.

Intracardiac and Rectal Temperatures.—Whereas the temperature of the peripheral tissues may vary widely in man, the temperature of the deep tissues, or of a critical deep tissue, remains fairly constant under widely varying conditions. The location of the critical deep tissue, whose temperature probably determines that of other tissues, is not known, but there is much evidence that it is in the diencephalon. While rectal temperature has been considered to be a good index of deep and critical tissue temperatures, it often appears to be unsatisfactory, as indicated by the onset of such compensating mechanisms as peripheral vasodilatation and sweating before a rise in rectal temperature has occurred, and, conversely, in subjects who are cooled, the presence of vasoconstriction and pilomotor activity before a fall in rectal temperature. Measurements of the temperature in the right side of the heart and in the deep vessels leading to this part of the heart, in the femoral artery, and in the rectum of 24 afebrile subjects showed that 1. There is a gradient of increasing temperature in the larger veins as they approach the heart. 2. Temperatures within the right side of the heart and pulmonary artery are equal. 3. Rectal temperature exceeds intracardiac and deep intravascular temperatures by a small but significant amount. 4. Temperatures in the veins draining the liver and brain are higher than the temperatures in the veins into which they drain, and they equal rectal temperature. The differences between rectal and intracardiac temperatures are not large enough to be of clinical importance in afebrile subjects, but preliminary observations suggest that during fever rectal temperature may exceed intracardiac temperature by up to 0.8 C. The data suggest a further study on rectal temperature in relation to the average deep tissue temperature and the temperature of the critical tissue that initiates thermoregulating mechanisms.

Cutaneous Effects of ACTH and Similar Steroids.—Although corticotrophin (ACTH), cortisone, and similar steroids improve at least temporarily certain skin conditions, such as lupus erythematosus, pemphigus, dermatomyositis, and exfoliative dermatitis, which were previously resistant to therapy, side effects, in the form of moon face, hirsutism, pigmentation, and acne, develop in patients treated for long periods with large doses of these hormones. Of 105 patients treated by Brunner and associates with these hormones, hyperpigmentation developed in 29, acne in 26, hypertrichosis in 12, seborrheic dermatitis in 3, and oiliness of the skin in several others. Thus, side effects indicating androgenic stimulation of cutaneous structures developed in a substantial proportion of the cases. Although there have been a variety of theories as to the cause of acne vulgaris and of seborrheic dermatitis, there is now much evidence pointing to androgenic hormones as causative factors.

Toxoplasmosis in Offspring of Infected Mice.—The introduction of Toxoplasma into the vaginal canal of the mouse causes local toxoplasmic vaginitis, followed by parasitemia and involvement of the peripheral maternal tissues and placenta. Parasites enter the fetal circulation from the placenta late in gestation and eventually produce disseminated lesions in the surviving offspring. Of 717 young mice studied histologically, 91 proved to have congenital toxoplasmosis. Lesions of toxoplasmosis appeared on the ninth postnatal day or later. They were hematogenous and similar to those observed in human congenital toxoplasmosis. The central nervous system was almost invariably affected, the lungs only slightly less often, and the heart and other tissues rarely. Large zones of inflammation, necrosis, and calcification in the brain, associated with a proliferation of Toxoplasma, duplicated features typical of the human disease. The infection reached its greatest intensity toward the end of the third week of life. As in human infantile toxoplasmosis, animals surviving the first phases of the disease showed evidence of healing or resolution of their lesions and a reduction or disappearance of Toxoplasma in histological sections. However, Toxoplasma sometimes persisted in the brain for long periods, in one instance for 78 days. Many of the animals had an unusual form of hepatic degeneration characterized by severe fatty infiltration, atrophy, and necrosis of liver cells at the free margins and adjacent portions of the surface. The hepatic lesions were not due to a growth of parasites in the liver but were possibly the result of a secondary metabolic disturbance or nutritional deficiency intensified by the generalized toxoplasmic infection.

Aureomycin and Vitamin B_6.—Rats fed pyridoxal or pyridoxamine incorporated into the basal ration grew less than rats fed equimolar amounts of pyridoxine. The addition of vitamin B_{12} to the basal ration did not alter the relative activities of the three forms of vitamin B_6. Aureomycin increased the growth of rats fed low levels of pyridoxine. It caused a decided increase in the growth of rats fed limiting amounts of pyridoxal or pyridoxamine. In the presence of the antibiotic the three forms of vitamin B_6 were approximately equal in growth-promoting activity. Aureomycin may act to prevent utilization or destruction of the growth-promoting nutrient vitamin B_6 by intestinal micro-organisms, thus increasing the amount available to the rat, and a similar action directed toward other known and possibly unknown food factors may explain in part the growth-promoting effects of antibiotics in crude rations.

Antabuse in Alcoholism.—Wexberg and associates discuss the use of antabuse (tetraethylthiuram disulfide) as an adjunct in the rehabilitation of alcoholics and stress that the patient must have at least average intelligence and must realize the risk he incurs should he return to drinking alcohol while taking antabuse. The patient's intelligence and motivation should be ascertained by psychological tests (e. g., Rorschach and thematic apperception tests). Psychiatric inquiry should also be used. This covers the patient's early history, social adaptability, educational level, work status, marital relations, religious background, and the development of the drinking problem. A complete physical survey is also needed and should include electroencephalogram, electrocardiogram, test of basal metabolic rate, liver and kidney function studies, and a glucose tolerance test. Contraindications to the use of antabuse are diabetes mellitus, cirrhosis of the liver, chronic or acute nephritis, myocardial failure, coronary sclerosis, pregnancy, epilepsy, and exophthalmic goiter. The patient must not drink for four or five days before antabuse is given. The first dose of the drug is 2 gm. This is decreased by half a gram each day to the maintenance dose of about 0.75 gm. The drug is given daily before breakfast. On the eighth day of treatment the patient is given 15 cc. of 90-proof whiskey every 15 min. After about three doses a reaction follows, the peak of which is reached in 30 to 60 min. The first and second tests with alcohol should be made in a hospital. Should the antabuse-alcohol reaction be too severe, 1,000 cc. of 5 per cent glucose in isotonic sodium chloride solution with 1,000 mg. of ascorbic acid should be given intravenously. Ephedrine, 24 mg., should be given intravenously if the blood pressure drops alarmingly. So that possible insidious toxic effects of the drug may be discovered, complete blood cell count, liver function studies, basal metabolic rate determination, and urinalysis should be done at frequent intervals.

Rice Diet in Hypertension.—The effect of the rice diet in two groups of outpatients with essential hypertension is evaluated. The first group (56 patients) was started on the diet in 1947, the second group (41 patients) in 1948. Of the total 97 patients, 28 adhered strictly, 35 moderately, and 34 not at all. In two years' time, which must be considered a brief and preliminary follow-up in essential hypertension, two of the strict adherents had maintained improvement in blood pressure by Kempner's criterion, a reduction of 20 mm. of mercury in mean arterial pressure. Three of the group had died; in nine, the disease had progressed, and in four had seemingly remained stationary. In a random group of patients treated on a conservative medical program, the authors could easily match these results, unless the group were weighted with cases of malignant hypertension. They believe that the rice diet is unpleasant and expensive for the patient because of weekly visits to the physician, demanding on the physician, and potentially dangerous. Nevertheless, the rice diet in some patients with severe hypertension apparently causes dramatic reversal of the disease process. It seems that to justify so rigorous a treatment it must be matched by the actual or impending rigors of the disease.

Untoward Reactions to Tests for Pheochromocytoma.—Fifty-six separate pharmacologic tests with adrenolytic substances were done on 18 hypertensive and three normotensive patients suspected of having pheochromocytoma. The test substances were injected intravenously. The injection time for piperoxan hydrochloride (933 F) and tetraethylammonium bromide was two minutes. The N,N-dibenzyl-beta-chlorethylamine (dibenamine®) was added directly to 500 cc. of isotonic sodium chloride solution and infused over a two-hour period. Tests were made under resting but not basal conditions. Frequent blood pressure readings were taken prior, during, and after the injection of the test substance. Untoward severe but nonfatal reactions were observed in four patients. In the first patient a rise in blood pressure exceeded 300 mm. of mercury immediately after the administration of 3 and 5 mg. of 933 F. The second patient received 17 mg. of 933 F, and acute pulmonary edema promptly developed. The third patient had anuria for 14 hr. after receiving dibenamine®. The fourth patient had a pronounced hypotensive reaction after receiving tetraethylammonium bromide. The relatively high incidence of toxic reactions in this series was probably due to the type of patients studied. Pharmacologic tests for pheochromocytoma with adrenolytic substances are not without danger, and they must be used with caution.

Treatment of Endocarditis.—Antibiotic treatment was given to 11 patients with subacute bacterial endocarditis. All patients were treated with aureomycin or chloramphenicol (chloromycetin®), either initially or after other antibiotics had failed to control the infection. The dose depended on the sensitivity in vitro of the infecting organism. The average dose of aureomycin was 0.5 to 1 gm., and of chloramphenicol 1 gm., both given orally every six hours. In two patients who could not tolerate the oral route aureomycin was administered intravenously. In three patients, treatment with chloramphenicol was initiated with a priming dose of 1 gm. every hour for four doses. The duration of treatment, which varied with each patient, was from eight to 35 days. In two of eight patients treated with aureomycin, the infection was considered to have been controlled by this drug. In both patients the blood cultures became negative on the day following institution of therapy. The infecting organisms in both patients were very sensitive strains of Streptococcus viridans. In these two patients the follow-up period was 11 and 12 mo. and there was no relapse. Aureomycin failed in the remaining six patients, in three of whom Str. faecalis was the infecting organism. Two of these patients were subsequently cured by large doses of penicillin. Chloramphenicol was used in five patients. A definite cure was effected in only one patient. Blood cultures became negative within 24 hr. after institution of therapy, which lasted 35 days. This patient was followed for five months after discontinuation of the drug, and there was no evidence of relapse. All patients treated with aureomycin had gastrointestinal symptoms, including anorexia, nausea, vomiting, or diarrhea. In general, chloramphenicol was more readily tolerated than aureomycin. Only one patient complained of nausea, and in two a mild maculopapular rash developed. Aureomycin and chloramphenicol may effect a bacteriologic cure in certain cases of subacute bacterial endocarditis due to a sensitive organism. An organism found to be sensitive to aureomycin and chloramphenicol in vitro will not necessarily respond in vivo. In the small series of patients reported on, aureomycin and chloromycetin were not effective when penicillin had previously failed, but penicillin was effective when these antibiotics did not control the infection. Patients had better symptomatic results with penicillin. Results indicate that penicillin is the antibiotic of choice in the therapy of subacute bacterial endocarditis due to Str. viridans and Str. faecalis. If large doses of penicillin or the combination of penicillin and streptomycin prove ineffective, aureomycin or chloramphenicol should be tried if in vitro studies are favorable.

Pregnenolone in Rheumatoid Arthritis.—Twenty patients with rheumatoid arthritis and one with polyarticular gout were treated as follows: Fifteen received daily intramuscular injections of an oily or aqueous suspension of the steroid pregnenolone in doses ranging from 100 to 600 mg. Two patients received two daily injections up to a total of 1,200 mg. per day. The injections were continued for four to eight weeks. Six patients were given 21-acetoxypregnenolone in daily intramuscular injections of an aqueous suspension in doses ranging from 100 to 300 mg. for two to four weeks. In addition, a course of corticotrophin (ACTH) was given to nine patients in doses of 15 mg. subcutaneously every eight hours for two to three weeks. Only one patient treated with pregnenolone felt much better at the end of the two months of treatment. In all other patients, the injections of pregnenolone and 21-acetoxypregnenolone did not produce any noticeable improvement of joint function, gain of weight, or return of the sedimentation rate to normal or even noticeably lower values. The various blood constituents examined, such as hemoglobin and white blood cells, also remained unchanged. Rheumatic nodules did not disappear, although one patient showed decrease in number and size of nodes under treatment with pregnenolone. All nine patients treated with coricotrophin after previous treatment with pregnenolone or 21-acetoxypregnenolone made a rapid clinical recovery. Neither pregnenolone nor 21-acetoxypregnenolone produced a sustained beneficial effect comparable to that obtained with corticotrophin. Side effects observed in the use of pregnenolone or 21-acetoxypregnenolone were rare and usually were only painful sensations at the site of injections. Repeated injections caused formation of firm lumps sometimes lasting several months. Prolonged menstrual flow occurred in two patients. Pregnenolone and 21-acetoxypregnenolone do not represent lastingly effective and innocuous drugs for the treatment of severe active rheumatoid arthritis.

Fallacies in Acute Appendicitis.—A study of acute appendicitis was begun at New Orleans Charity Hospital in 1933, and 7,613 cases were analyzed in seven series. The total mortality rate was 4.46%, but it has declined successively from 6.58 to 1.7%. Despite this decline, the incidence of complications is increasing. This may be partly explained by the fact that many patients entered the hospital after the first 24 hr. of illness and that more than a third had taken purgatives, sometimes on the advice of physicians. Enemas were also ordered by physicians, and icebags are again being used. Apparently, many physicians are not aware that appendicitis is often an atypical disease. The physician should not wait 12 hr. to "re-evaluate" a patient; operation should be performed at the end of six hours if acute appendicitis cannot be ruled out. That the mortality rate has declined despite the aforementioned deplorable tendencies is largely due to intensive supportive therapy and to chemotherapy. The limitation of chemotherapy is stressed: many delays in surgical treatment must be attributed to its unjudicious use. The author favors prompt operation, because: 1. The diagnosis of rupture of the appendix is inaccurate. 2. It is impossible to determine whether peritonitis is spreading or is localizing. 3. A localized abscess may rupture intraperitoneally and cause death. 4. A properly performed surgical procedure that removes the source of infection is safer than continued entrance into the peritoneal cavity of infection from a ruptured viscus. 5. The results of conservative therapy are no better than the results of prompt surgery. While the curative properties of the antibiotics should be utilized, it should be remembered that they are ineffective in areas of inadequate circulation, such as in gangrenous processes and walled-off abscesses. In uncomplicated cases of acute appendicitis these agents are adjuncts to, not substitutes for, surgical procedures.

*Comparative Study of Oral Terramycin and Aureomycin Therapy of Gonorrhea in Males. M. S. Beinfield, L. T. Wright, F. R. DeLuca and others.—p. 1054.

Steroids in Rheumatoid Arthritis.—Of the 67 patients who received a total of 109 therapeutic courses with steroids, 55 had typical peripheral rheumatoid arthritis, seven had rheumatoid spondylitis, four had rheumatoid arthritis associated with psoriasis, and one had advanced osteoarthritis. The steroids were estosterone, desoxycorticosterone acetate combined with ascorbic acid, 21-acetoxypregnenolone, pregnenolone, 16-dehydro-pregnenolone, and cortisone. Thirty-four patients received only one course of treatment; the other 33 received more courses. Improvement occurred in some patients with each steroid, but in no group was the response comparable to that obtained with cortisone. Twenty-two of the 24 patients who received cortisone had previously failed to respond satisfactorily to the other steroids. No severe toxic symptoms resulted from cortisone therapy in this group.

Oral Terramycin and Aureomycin for Gonorrhea in Males.—Terramycin or aureomycin was orally administered to 260 unselected male patients in whom gonococcic urethritis had been proved by smear and culture. Three different dosage schedules were used. The first consisted of a total dose of 2 gm. given in four divided doses of 0.5 gm. at four-hour intervals. In the second, 500 mg. were given initially at about 10 a. m., a 250 mg. capsule was given at 2 p. m., and another 250 mg. capsule at 6 p. m. of the same day. In the third schedule a total dose of 1 gm. was given in divided doses of 0.5 gm. at six-hour intervals. An equal number (130) of the patients were treated with each of the drugs. The percentage of cure with both terramycin and aureomycin was between 95 and 96%, or as high as that obtained with intramuscular injections of penicillin. Effectiveness, lack of toxicity, and ease of administration make orally administered terramycin and aureomycin the agents of choice in this condition.

Corneal Tattoo for Restoration of Eye Color.—Some persons with corneal scars who have reduced sight or no serviceable vision and who are not acceptable for a corneal graft cannot tolerate a prosthetic shell because the calcareous deposits projecting from the scar rub against the prosthesis and cause pain and uncontrollable lacrimation. In the business and social world, the person with an unsightly "poached-egg-eye" may be seriously handicapped and may consequently have psychic disturbances. Even though an eye may be blind, tattoo of a corneal scar will conceal a conspicuous and embarrassing deformity. In a series of experiments on rabbits Pickrell and collaborators had tattooed both scarred and normal corneas. They describe the procedure and show photographs of human subjects showing the results of the implantation of pigment to match the normal eye. The method has been used more than 75 times during the past six years, without complication. Patients with congenital opaque cornea, post-traumatic corneal scars, conjunctival flaps, operative defects of the iris, heterochromia, polychromia, and coloboma have been tattooed with gratifying results.

Sulfoxone and Glucosulfone in Toxoplasmosis.—On the assumption that toxoplasmosis is essentially a disease of the reticuloendothelial system a therapeutic trial with sulfoxone (diasone®) sodium and with glucosulfone (promin®) sodium seemed justified, because these sulfones had proved beneficial in leprosy, also a reticuloendothelial disease. Sulfoxone was given subcutaneously, and glucosulfone (0.5%) was put in the food. Both drugs not only suppressed the symptoms but repeatedly eliminated the carrier state. Mice treated with glucosulfone survived over a year, but sulfoxone appears to be less toxic and more potent, since it protected mice when therapy was delayed for one-third of the survival time of untreated mice.

Neoplasms in Thyroid After Injection of Radioactive Iodine.—Examination of 10 rats killed 18 mo. after a single injection of 400 µc of radioactive iodine revealed the following changes in the thyroid gland: 1. Hürthle-like elements (previously observed in thyroid of rats killed eight months after a single injection of I^{131}) were evident in the parenchyma of all glands. 2. Multiple adenomas, apparently benign, were found in the thyroids of two rats. 3. Two types of anaplastic, nonencapsulated neoplasms, one of which was invading adjacent thyroid tissue, were also found in the thyroids of these two rats. The possibility that the trapped I^{131} might initiate neoplastic changes in the thyroid gland has been recognized by many clinical investigators, who have mentioned the need for caution in the use of radioiodine for diagnosis and treatment of Graves' disease.

Phenylthiocarbamide Test in Doubtful Paternity.—Phenylthiocarbamide is known to divide the adult population into two groups, those capable of tasting its intense bitterness (T) and those to whom it is tasteless (t). The capacity for tasting or failing to taste the compound is inherited according to Mendelian laws. It is demonstrated that the ability to taste this compound is demonstrable in early infancy, and it is suggested that such data can be profitably employed in cases of doubtful paternity in situations where a tasting child is born to a nontasting mother.

Lateral Herniations of Cervical Disks.—The syndrome caused by lateral herniation of cervical disks is constant, and the specific nerve root involved can usually be identified clinically. These patients often have symptoms of severe shoulder and arm pain. They may also have neck, occipital, and chest pain on the involved side. Stiffness or a "crick" in the neck may be or have been present. Often the physician's attention is directed entirely to the shoulder and upper extremity. Sometimes the pain extends into the hand, but more commonly numbness and paresthesias are present in the hand. The vast majority of cases are amenable to conservative medical therapy. In cases not amenable to medical therapy, the diagnosis and the specific nerve root involved can be verified by pantopaque myelography and relief obtained by surgical removal of the herniated cervical disk. Two cases are presented that illustrate some of the variations and problems encountered in this condition.

Murine Typhus Fever.—After commenting on the epidemiology of old world typhus and murine typhus Hedden discusses the present status of the problem of murine typhus in South Carolina. He stresses that this is still predominately a disease of cities and towns in South Carolina. The highest incidence of typhus in South Carolina is in the eastern half of the state. Trucks carrying rats as well as grains and produce have undoubtedly played a part in carrying typhus to out-of-the-way communities. Annual reports of the South Carolina State Board of Health beginning with the year 1937 reveal concern over the increase in incidence of typhus fever. In 1939, a total of 232 cases was reported from the entire state. In July, 1942, the significant increase in incidence of typhus fever and the war effort caused the United States Public Health Service to form a typhus control unit. In 1945, typhus control activities were reorganized. Morbidity statistics for typhus fever in South Carolina were considered to warrant federal assistance. Typhus control measures, such as rat poisoning, dichlorodiphenyltrichloroethane (DDT) dusting, and rat-proofing appear to be reducing the incidence of the disease in South Carolina.

Prefrontal Lobotomy Compared with Transorbital Lobotomy.—Freeman compares the results of prefrontal lobotomy in 624 patients (702 operations) with those of transorbital lobotomy in 316 patients. Lobotomy fails mostly because, in deteriorated patients, it is impossible to place the lesions sufficiently far back to relieve the psychosis without at the same time damaging those personality characteristics that are necessary for living in a social environment. Patients with dementia precox are somewhat less likely to respond to prefrontal lobotomy with effective social capacity than those suffering from affective disorders like involutional depressions or from various types of psychoneuroses. Nevertheless, more than one out of four patients with dementia precox is leading a socially useful existence after the operation. About 75% of the 624 patients have benefited. The failures are mostly in those patients in whom deterioration before operation was too great to allow much hope of successful adjustment. Prefrontal lobotomy is a major surgical operation and is usually performed by the neurosurgeon. In 1946, after much study of the anatomic relationships, Freeman began to use the transorbital approach, the technique of which is quite simple. Recovery from transorbital lobotomy is prompt. Hospitalization lasts only a day or two and the swelling and discoloration of the eyelids disappear within two weeks. Disabled patients are back at their accustomed tasks by the end of a month. The mortality rate following transorbital lobotomy is less than 2%. The over-all results are about the same for the two types of operation, 68% of patients being able to live outside of institutions after transorbital lobotomy as compared with 70% after prefrontal lobotomy. The minor operation is less successful in dementia precox cases but more successful in the other types of mental disorder. Transorbital lobotomy is the method of choice in institutional practice.

Results of Topectomy.—Topectomy is a fractional ablation of the frontal lobe cortex, with resection in only the gray matter. The amount of tissue removed is usually between 25 and 35 gm. on each side. Hoch describes psychiatric observations made on 105 patients who had been subjected to topectomy by Dr. Pool and his staff. Most of the patients subjected to topectomy had schizophrenia of the hebephrenic, catatonic, paranoid, mixed, or simple forms. One-fifth (21) of the patients had a pseudo-psychoneurotic form of schizophrenia. All patients operated on had been sick for several years and had received shock treatment, psychotherapy, or both. Sixty per cent of the patients remained unimproved. Thirty (29%) were sufficiently improved to be provisionally released. Nearly two-thirds of those who had no preoperative deterioration showed good improvement, whereas among the greatly deteriorated patients only 7% showed improvement. Topectomy was effective in those with obsessive and phobic symptomatology. It is believed that topectomy would give better results if it could be done on schizophrenic patients in whom other treatments have failed but who have not yet greatly deteriorated. Obsessive, depressive, and phobic symptoms seem to respond best to topectomy, whereas aggressive patients seemingly respond better to lobotomy than to topectomy. The clinical impression is that pronounced alterations in personality, especially the well-known apathy, complacency, and emotional dulling, do not occur as frequently with topectomy as with lobotomy. Adverse personality changes after topectomy are seen more commonly in deteriorated schizophrenic patients than in those with a relatively well preserved mentality prior to the operation.

Prevention of Rheumatic Fever.—All patients admitted to the hospital of an air base for respiratory disease were examined for the presence of exudate on the tonsils or on the pharyngeal wall. Of 2,340 such patients about half received penicillin treatment and the others comprised the control group and received no specific treatment. Of the patients treated with penicillin, definite acute rheumatic fever developed in only two. In contrast, the disease developed in 28 of the untreated patients. The diagnosis of possible acute rheumatic fever was made in three patients in the treated group and in seven patients in the untreated group. Penicillin also suppresses the antistreptolysin "O" response and eradicates the streptococci in many cases. These data seem to establish the fact that penicillin therapy for acute streptococcic infections will almost always prevent the subsequent occurrence of rheumatic fever. Recommendations are made for the prevention of rheumatic fever in streptococcic infections.

Electrokymographic Study of Delay of Ejection in Intraventricular Blocks. M. Segers and J. Hendrickx.—p. 150.

Myocardial Injury at Cardiac Catheterization.—The patient whose case is reported was a boy, 8, who was referred for diagnosis of a suspected congenital heart malformation. A harsh systolic murmur was heard and felt in the left second costal interspace. The electrocardiogram showed a right axis deviation, but the heart was roentgenologically within normal limits. There was some increase in pulmonary vascularization. Carotid aortography showed a patent ductus arteriosus. Cardiac catheterization suggested that there was a shunt between aorta and the pulmonary artery, probably a patent ductus arteriosus, and a pulmonary stenosis. During the catheterization, which was performed without difficulty, the electrocardiogram showed instability of the pacemaker, not only with variations in the P-Q interval and the P-wave itself but also with changes in the QRS-complexes, which simulated preexcitation but probably represented nodal rhythm with or without additional intraventricular, or septal, conduction disturbances. Concurrently, but in all likelihood independently of these conduction disturbances, the electrocardiogram also revealed marked S-T depressions, which may be considered as representing subendocardial injury. Intracavitary pressure readings taken simultaneously showed pronounced reduction of right ventricular systolic pressures. Although this was probably partly due to unknown mechanical factors relating to the position of the catheter tip, the authors felt it was more likely due to functional myocardial insufficiency, related to and perhaps induced by the simultaneous subendocardial injury. That cardiac catheterization may initiate lesions of the endocardial surfaces was recently proved in dogs. The authors feel that in more irritable hearts than this boy's such myocardial injury may constitute a grave danger.

Nylon Arthroplasty in Arthritis.—In chronic rheumatoid arthritis, disability of the knee usually begins with flexion deformity and progresses to subluxation, destruction of the articular surfaces, or ankylosis of the joint. While ankylosis in full extension does not greatly interfere with walking or standing, it seriously disturbs rising and sitting. Attempts have been made to produce motion in the knee joint by either resection or reshaping of the articular surfaces and the interposition of fascia lata. In seeking a more durable substance for interposition between the articular surfaces, the authors found that most plastic films caused slight irritation when inserted into the rectus sheath of rats but that there was no irritation with the nylon membrane. Small pieces of nylon were then attached to the denuded undersurface of the patella in rabbits. No inflammation was observed in the joint and the animals seemed to use the knee in a normal manner. By modifying a procedure described by Hass in 1930 the authors then developed a simple method of forming new knee joints, employing nylon films to prevent adhesions of the joint surfaces. They performed this operation in 33 patients. In the group with bony ankylosis all except two obtained a satisfactory range of painless motion. Those with severe osteoarthritis of the knee now have a wide range of painless motion, and the authors believe that the operation will have a wider application in severe osteoarthritis. To date they have observed no reaction to the nylon membrane. A firm layer of fibrous tissue develops under the nylon. Early active motion is essential to the success of this procedure, and careful postoperative observation is required if complications are to be prevented.

Pregnancy in Ankylosing Spondylitis.—Hart and associates describe and discuss the management of pregnancy in two patients with ankylosing spondylitis. One woman, with a mild form, had an easy labor, but her disease appeared to progress during cyesis. The other, with severe ankylosis, was delivered of a normal child by cesarean section in the 36th week. Her vital capacity rose slightly during pregnancy, and, although her thorax was completely fused, no respiratory distress was experienced. In neither case was there symptomatic improvement or true remission during pregnancy.

Laughter (Sham Mirth) in Cerebral Disease.—Four cases are described in which attacks of laughter occurred in association with organic cerebral disease, and similar cases from the literature are quoted. The episodes of laughter are considered to be fits comparable with Jacksonian (motor or sensory) fits. The patient's emotional state at the time of such an attack is not that appropriate to laughter—the apparent mirth is "sham." In every case in which there were indications of the site of the lesion, it was so placed that it might affect the hypothalamus, and these cases give support to the view that the motor center for laughter is situated in or near the hypothalamus. There was no indication that the attacks depended on any gradual loss of control, such as occurs with cerebral arteriosclerosis, pseudobulbar palsy, or amyotrophic lateral sclerosis. All the four patients were young (18 to 25 yr.), whereas in cases of uncontrolled laughter due to removal of inhibitory control the patients are mostly middle-aged or elderly. Another feature of these cases was their sinister character. In the first case the attacks of laughter were soon followed by death, in the second by a severe hemiplegia, in the third further subarachnoid hemorrhage threatened, in Andersen's case the laughing led immediately to coma and death, and in the fourth case, reported here, it led to coma and slow death. It seems that the "laughing center" must lie close to vital structures.

Benign Giant-Cell Synovioma.—The occurrence of benign giant-cell synovioma is reported in 85 patients, 55 of whom were females. The site of election of the lesion is the hand (69 patients) and particularly the digits, which were involved in 56 patients. The extensor aspect of the digits was as frequently involved as the flexor, the synoviomas on the extensor aspect probably arising from interphalangeal joint synovium. The average duration of the tumors at the time of the first consultation was two years and seven months. Nineteen (40%) of the 48 patients from whom information as to injury was obtainable gave a history of trauma to the site of growth. Benign giant-cell synovioma arising from a tendon sheath or small joint has a villous structure in its early stages, which often persists. Eventually, owing to the lack of space in the synovial cavity, the tumor grows outward as an encapsulated neoplasm. Encapsulation is often absent on the deep aspect, where the tumor blends with its synovial attachments. The most characteristic histological feature is the differentiation into synovial-lined spaces within the tumor substance. Microscopically the tumors removed from the author's patients included all gradations from the typical benign form to a more cellular variety of intermediate malignancy, which in turn is closely related to the malignant synovioma. Fifty-four patients were followed up after the primary excision of the tumor, and recurrences were observed in 25 patients (48%). The interval between the excision varied from a few weeks to six months. Tumors that recurred were almost invariably of the more cellular variety. Incomplete excision of the tumor or its synovial attachments is probably the most important cause of recurrence. Local excision is indicated in every case whether primary or recurrent, provided this is anatomically possible. The lesion is to be considered truly neoplastic, but it does not metastasize. Blood-cholesterol was not elevated in 17 investigated cases. The lipoid accumulations and the siderosis commonly observed in these tumors are of degenerative or traumatic origin or both and are purely local phenomena, in part related to the well-known phagocytic power of the synovial cell.

Reduplication of the Transverse Colon.—A girl 5, with severe abdominal distention, intractable constipation from birth, and poor general health is reported on. Examination of her abdomen revealed marked tympany and intermittent gross peristaltic waves. The rectum was empty of feces but distended with gas. The outstanding feature of the roentgenogram was a huge sac in the upper left abdomen showing a fluid level surmounted by a gas collection. Laparotomy revealed a large diverticulum arising from the proximal segment of the transverse colon. The ballooned blind sac of the diverticulum filled the upper left abdomen, compressing the stomach and thrusting up the diaphragm, and was covered by remnants of the transverse mesocolon. The narrower "stalk" reduplicated the transverse colon and, in its proximal segment, had a common lumen. The muscular coats were clearly conjoined and the vascular supply inseparable. Resection was the only feasible procedure. The child made an uninterrupted recovery and during a nine month observation period showed normal bowel function.

Hemophilia with Normal Coagulation Time.—The absence of antihemophilic globulin in hemophilic blood can be used as a diagnostic test for this condition, if minimal amounts of the blood of a patient suspected of having hemophilia are added to known hemophilic blood. If the suspected blood proves incapable of correcting the coagulation time and prothrombin consumption defect, the patient probably has hemophilia. If its ability to correct these defects is less than that of an equal proportion of normal blood, the patient probably has the hemophilic defect, but in less degree. By the use of this test in hemophilic patients Merskey showed that varying grades of the hemophilic defect exist. At the one extreme were the classic hemophiliacs with prolonged coagulation time, grossly defective prothrombin consumption, and inability to correct hemophilic blood; at the other extreme were patients with normal coagulation time, a much milder prothrombin consumption defect, and a partial ability to correct hemophilic blood. This paper is a report of 14 cases of hemophilia occurring in eight families in whom coagulation times and the results of other common blood tests were normal in the majority of instances. The blood of these patients was ineffective in correcting the defects of known hemophilic blood, however, and clinically there was no doubt that these persons had hemophilia. The author shows that it is dangerous to rely on the common bleeding and clotting tests to exclude hemophilia.

Inclusion Bodies in Warts.—On the assumption that warts were due to a virus Lyell and Miles looked for inclusion bodies in sections of warts taken from 10 patients. They found that five of the patients' warts contained eosinophilic intranuclear and intracytoplasmic bodies in the prickle-cell layer and in the belief that these were inclusion bodies the authors named these warts type I, for "inclusion." Warts from the remaining five patients were devoid of these eosinophilic bodies, and such warts were named type B, for "banal," because of their commonplace histology. Subsequently, the warts from 102 consecutive patients were examined. The type I warts were mostly plantar, palmar, subungual, or on the pulp of a digit, whereas the type B warts were predominantly common warts of the fingers, face, scalp, and knees. The type I warts were deeply set in the skin, in contrast with type B warts, which were set superficially. Type I warts looked like little molehills with domed tops, while the type B ones were typical warty excrescences. Type I warts lay in a flask-shaped cavity, wider at the bottom than the top, while type B warts lay in a saucer-shaped depression. The authors are uncertain of the relationship between the two types, but the recurrence of some type I warts as type B and the discovery of an intermediate type suggest that type I warts are a variety of type B. However, other evidence (a transmission experiment and a clinical case in which the warts bred true) indicates an absolute distinction between the types. The type I warts are the same entity as the myrmecia of Celsus, the vascular excrescence of Durlacher, and the plantar wart of Dubreuilh. Plantar warts called the mosaic type are histologically type B. It is suggested that the term "verruca vulgaris" be confined to type B warts and that type I be renamed "myrmecia."

Aureomycin and Chloramphenicol in Herpes Zoster.—Forty-four patients with herpes zoster were divided for treatment in four groups of 11 patients each. The first group of patients served as controls and was given dextrose. The second group was given 2 gm. of aureomycin daily for six days. The third group received 4 gm. of aureomycin daily for four days. The fourth group was given 2 gm. of chloramphenicol (chloromycetin®) daily for six days. The controls were selected at random, and the observers did not know which patients were in this group. No significant difference was found between the groups in respect to amount and duration of herpetic pain, paresthesias, or the appearance of new herpetic lesions. Treatment with either aureomycin or chloramphenicol within the first week of the rash shortened the pustular stage so that desquamation was earlier and scarring less. All the patients treated with aureomycin and all but two of those treated with chloramphenicol were free from secondary infection, which was present in all the controls. The effect of the antibiotics thus can reasonably be attributed to their action on the secondary infection. Two patients with dramatic amelioration of symptoms have been reported on in detail; one was treated with aureomycin, and the other was a control. In view of these results, it seems that such expensive drugs should be employed only in very severe cases, particularly ophthalmic zoster, occurring in elderly or debilitated patients.

Expectant Treatment of Perforated Peptic Ulcer.—Expectant treatment was practiced in 40 unselected patients with acute perforated peptic ulcer, of whom 32 had duodenal ulcers, seven had gastric ulcers, and one had carcinoma of the stomach. Treatment consisted of immediate aspiration of the stomach contents, continuous gastric suction, repeated injection of morphine, and intravenous infusion. The patients were kept under constant control during the first 48 hr. of expectant treatment, and laparotomy was performed if there was no obvious clinical improvement. Four patients died, and the treatment failed in five patients. Thirty-one of the 32 patients with perforated duodenal ulcer recovered under expectant treatment, but only one out of four patients with anterior perforations of the stomach survived. In 13 of the 36 surviving patients either localized pneumonitis or basal collapse developed. The incidence of chest complications thus was approximately the same as that following surgical treatment of perforated peptic ulcer. As the result of these experiences the author has now abandoned the expectant method of treatment in favor of early laparotomy in every case. If the perforation is found to have sealed adequately, either by adhesion to the liver or by means of an omental plug, the abdomen is closed again with no further surgical intervention, and conservative treatment is then instituted. Actual operative closure of the perforation is normally reserved for cases in which there is apparently no spontaneous sealing, though it is done routinely in every instance of anterior gastric ulcer.

Diagnosis of Cancer of Large Bowel.—Cancer of the large bowel is the commonest variety of cancer and accounts for 15% of all deaths from cancer. Since early stages of cancer cause no symptoms, detection depends on careful physical examination. Seventy per cent of the cancers occurring in the colon or rectum are either palpable to the examining finger or within reach of the sigmoidoscope. While a cancer may sometimes be detectable in an unprepared rectum, it is absolutely impossible to eliminate the likelihood of cancer being present in a patient whose bowel has not been properly evacuated. The local examination in women should always commence with the vagina, because it frequently is possible to obtain considerably more information about a rectal cancer from a vaginal examination than by an examination of the rectum proper. In addition to the digital examination, sigmoidoscopic examination has proved very useful, but the author feels that x-ray investigation plays no part in the diagnosis of cancer of the rectum. If examination of the rectum discloses no cancer, then the colon should be investigated. Here a thorough roentgenologic study, including both fluoroscopy and radiography, is advisable after administration of a barium enema. Barium given by mouth may cause intestinal obstruction and even perforation. The following symptoms are suggestive of cancer of the colon or rectum: bleeding, alteration in bowel function, and abdominal discomfort. At the author's hospital, where 277 patients with cancer of large bowel or rectum were treated in the course of 14 yr., the proportion of patients with cancer of the rectum who were operable when the diagnosis was made has gradually increased to 72%. The hospital mortality has dropped to 3%, and 52% of all patients in whom resection was done have lived for five or more years. Essentially similar results have been obtained in patients with cancer of the colon. A small number of patients with rectal cancer are amenable to cure by irradiation.

Poison Ivy.—After discussing the terminology of the plants of the genus Rhus, which produce dermatitis, Clarkson says that nothing that approaches a cure has been added to the pharmacopeia. There is now enough evidence showing that injections of various extracts are of no value. Various ointments have been found helpful, but they do not cure. In the course of the disease erythema and itching appear 48 hr. after contact, reaching a maximum in four or five days; vesicles appear on the third day, last a week, and then gradually dry. The itching is usually gone in 10 days.

*Problem of Interruption of Pregnancy and Sterilization in Familial Erythroblastosis. P. Dahr.—p. 513.
*Sex Gland Hormones in Therapy. C. Kaufmann.—p. 519.

Pregnancy and Familial Erythroblastosis.—Experience with erythroblastosis in 700 families suggests that from the medical point of view interruption of pregnancy should be permitted only in a woman who already has given birth to one dead infant, who in the third to fourth months of a new pregnancy shows blocking (univalent) Rh antibodies the titer of which increases rapidly up to the end of the fourth month of pregnancy, and who during the first two months of her pregnancy had no Rh antibodies in her blood. Interruption of pregnancy should not be considered if the absence of blocking antibodies has not been demonstrated during the interval between the two pregnancies or during the first two months of the new pregnancy, because Rh antibodies found in one pregnancy may have been present continuously since a previous pregnancy. Sterilization of a woman from a family with erythroblastosis may be permissible from the social point of view, provided that there have been several stillbirths and that the birth of a healthy child apparently may no longer be expected. But even if in such a case sterilization would be legally permissible, it is not justifiable medically, because it is still possible that such a woman may give birth to a healthy child conceived from a Rh-heterozygous man or from any Rh-negative man.

Sex Gland Hormones in Therapy.—Psychosomatic interrelationship plays an important part in functional sex disturbances. Recognition of this fact is of greatest importance in therapy. Functional sex disturbances due to psychic injury resulting from changes of the environment are reversible in the majority of cases, once the injurious influence has been removed. Accurate determination of basal body temperature over a prolonged period of time is of diagnostic significance. Estrogenic substances are of great value for the removal of severe menopausal symptoms, the so-called functional endocrine disturbances. Although encouraging words and sedatives may be sufficient in half these patients, repeated injections of 10 mg. crystalline estradiol suspension in oil at three month intervals are recommended by the author for the other patients. Bleeding may be induced in women over 20 with amenorrhea of more than six months' duration by a single injection of either 10 mg. crystalline estradiol suspension or 50 mg. crystalline progesterone suspension. If bleeding does not occur within three weeks, six injections of 5 mg. of estradiol dipropionate over a period of 21 days should be combined with one injection of 50 mg. progesterone suspension on the 14th day; cyclic bleeding will be obtained by this method, provided that treatment is continued for more than three months. The implantation of even small doses of crystalline estrogenic steroids creates unphysiological conditions and is not without risk in women whose uterus has not been removed. Treatment of functional bleeding with large doses of 200 to 400 mg. of progesterone seems to offer a favorable prognosis. In patients with dysmenorrhea caused by endometriosis, pain relief may be obtained by administration of 150 mg. of testosterone in six divided doses of 25 mg. The use of estradiol, progesterone, and testosterone in physiological doses is without risk and is not carcinogenic. It is not likely that abortion may be induced by estrogenic substances.

Comparative Study of Wassermann, Kahn, and Kline Tests.—Russo performed the Wassermann, Kahn, and Kline tests on a total of 8,802 specimens of blood serum of treated and untreated syphilitics. The results of these tests were in agreement in 7,990 samples (92.3%) and divergent in 812 samples (7.7%). The Wassermann test agreed with the standard Kahn and diagnostic Kline in 91.9% and 91.2% of the samples, respectively. The standard Kahn agreed with the diagnostic Kline in 98.2% of the samples. Positive results were obtained in 30.1% of samples with the Wassermann test, 37.0% with the Kahn test, and 37.7% with the Kline. The results show that Kline's microflocculation test is the most sensitive and the Wassermann the least sensitive.

Giant-Cell Granuloma of Pituitary.—Doniach and Wright report two cases of giant-cell granuloma of the anterior pituitary. In 1917 Simmonds discovered and described four cases of this disorder; in 1949 Sheehan and Summers grouped 18 cases, including Simmonds' four cases, under the heading of "giant-cell granuloma." The present authors agree with Sheehan and Summers that "the group may include lesions due to several different causes, such as syphilis, tuberculosis, or sarcoidosis, but that most of the cases appear to be examples of a specific disease process whose etiology is unknown." The studies of Doniach and

Wright led to no positive conclusion as to the etiology of pituitary giant-cell granuloma. Like previous observers, they interpret the lesion histologically as a primary parenchymatous necrosis of the pars anterior of the pituitary rather than as a destructive infiltration by an infective granuloma, but they admit this interpretation is weakened by the finding of granulomatous lesions, admittedly differing in detailed morphology, in other parts of the body. Although tuberculosis, syphilis, and sarcoid were all considered as possible etiologic factors, none could be accepted or rejected.

*Streptomycin in Letterer-Siwe's Disease. R. P. Aronson.—p. 889.

Costal Chondritis.—Deane presents the histories of seven patients who had painful nonsuppurative swelling of costal cartilages, a disorder usually referred to as Tietze's disease, because Tietze first described this entity, in 1921. At that time malnutrition was regarded as a possible cause. The cases observed by Deane all involved the second costal cartilage, but other workers reported involvement of any, or in some cases several, cartilages from the first to the 10th. The second seems to be involved oftener than any other. Whether the swelling involves the cartilage or the perichondral tissues is difficult to determine. It is sharply demarcated laterally by the costochondral junction, over which tenderness may be more acute than over the cartilage. In all the cases referred to Deane a tuberculous infection was suspected, but in only one case was there evidence of such an infection, and in this case the pulmonary lesion was inactive. The swelling and pain gradually subside, but some residual swelling may remain indefinitely. Investigation of erythrocyte sedimentation rate, Wassermann reaction, and blood cell counts failed to yield significant findings. Though the pathological basis has not yet been determined, the patient may be reassured that the lesion is benign. No treatment is necessary except rest of the arm on the affected side and the application of heat when the swelling is painful.

Streptomycin in Letterer-Siwe's Disease.—Presenting a classification of the reticuloses, Aronson says that Letterer-Siwe's disease is one of the nonlipoid reticuloses, the main features of which are enlargement of liver and spleen, a hemorrhagic tendency that manifests itself as petechiae or purpura, generalized enlargement of lymph nodes, cyst formation and tumors in bones, progressive secondary anemia, and generalized hyperplasia of macrophages in spleen and other organs. The disease is seen only in infants and ends fatally. It is not hereditary. The case described here first appeared as a hemolytic anemia but was otherwise typical. The diagnosis was not made until histological examination of the spleen had been completed. Splenectomy appeared to arrest the hemolytic process, but otherwise the child's condition was not greatly altered. A preliminary examination of the spleen had suggested a diagnosis of sarcoidosis, and, as sarcoidosis is thought by some to represent an atypical response to the tubercle bacillus and the response to splenectomy had not been very dramatic, it was decided to try streptomycin. Treatment lasted five weeks. Seven days after streptomycin treatment started, the enlarged cervical glands were no longer palpable, the temperature had begun to settle, and for the first time the body was entirely free from petechiae. The child has remained well now for over two years. All previous cases have progressively deteriorated, the longest survival being two years. Though the etiology of Letterer-Siwe's disease is unknown, various kinds of sepsis or reactions to as yet undetermined toxins may be factors. The favorable response to streptomycin lends some support to this theory.

Cyanosis From Nitrates in Well Water.—This is the first report from England of well water cyanosis in infants. Two infants, 4 weeks and 6 weeks of age respectively, were given in their formulas water from shallow wells contaminated with coliform organisms and nitrates. Both became cyanotic and showed methemoglobinemia. One died before admission to the hospital, the other recovered following exchange transfusion. This condition is apparently limited to the first few weeks of life, during which time the physiological hypochlorhydria of infancy permits the growth of lower bowel organisms (Escherichia coli, Aerobacter aerogenes, and E. freundii) in the upper gastrointestinal tract. These organisms reduce ingested nitrates to nitrites, which are absorbed in the small intestine. The nitrites oxidize hemoglobin to methemoglobin, and the infant becomes cyanotic. Water containing more than 20 ppm of nitrates should be regarded as unsafe for infant consumption. Boiling does not reduce the nitrate content of such water. Once this type of cyanosis has developed in an infant, the recommended treatment is the intravenous injection of methylene blue, 1 or 2 mg. per kilogram of body weight.

Aniline Methemoglobinemia in Infants.—A sudden outbreak of cyanosis in 23 infants in the nurseries of a maternity hospital is reported. The cause was the absorption of aniline dye from fresh marking ink on diapers that had not been laundered. This had produced methemoglobinemia in the infants. After withdrawal of the incriminated diapers the babies were divided into three groups. One group was treated with methylene blue (1 to 2 ml. of a 1% solution given intravenously), another with ascorbic acid (50 mg. orally before each feeding), and the third group was left untreated. The babies treated with methylene blue responded dramatically. The ascorbic acid and control groups recovered at about equal rates but more slowly than the methylene blue group. Four of the premature infants required blood transfusions for anemia. One died two months later and at autopsy was found to have ulcerative enteritis, thrombophlebitis of the superior mesenteric and portal veins, and splenomegaly with fibrosis. Absorption of aniline dyes from laundry marking ink can be prevented if the article of clothing is laundered before use.

Familial Idiopathic Methemoglobinemia.—The authors report two cases of familial idiopathic methemoglobinemia in children aged 3½ yr. and 6 yr. respectively. Both were cyanotic from birth, and one was thought to have congenital cardiac disease. Both developed normally, however, and showed no dyspnea. No other available members of the patients' families were found to have methemoglobinemia. This supports the belief that the disease is inherited as a recessive character. The erythrocytes of these patients showed an abnormally low capacity to reduce methemoglobin in the presence of glucose or lactate and an abnormally low activity of diaphorase I (coenzyme factor I). This defect in the reducing system of the cells is thought to be responsible for the symptoms in this disease. Since there is a continuous slow oxidation of hemoglobin to methemoglobin in the blood, any decrease in activity of the reducing systems of the erythrocytes permits an accumulation of methemoglobin. The patients reported on were treated successfully with methylene blue and ascorbic acid.

Bulbar Poliomyelitis.—Both the incidence and the severity of bulbar lesions can vary in different epidemics of poliomyelitis. Among all poliomyelitis cases observed at Kelleher's hospital in 1947 a higher than usual proportion of bulbar cases was observed, but the severity of the cranial-nerve lesions was much less than had been anticipated from impressions of the danger of these lesions gathered in the prewar years. In 1949, on the other hand, he met with a disturbingly higher proportion of dangerous forms of bulbar attack. Not long ago it was accepted that patients with the more dangerous types of bulbar poliomyelitis would die, regardless of treatment. Recently, however, more favorable results have supposedly been obtained, both through a better recognition of the factors producing symptoms and through a better application of the principles of therapy. From experiences at his hospital and from a study of the American literature Kelleher believes that tracheotomy and other appropriate remedial measures should be considered for the cases of poliomyelitis in which dangerous bulbar lesions interfere with free oxygenation. The poliomyelitis team should include an anesthetist and a laryngologist, who should be prepared to perform tracheotomy as a carefully planned measure of prevention rather than as a cure of the dangerous sequelae of respiratory obstruction.

Paralytic Poliomyelitis Following Injury.—It has been established that in children recently subjected to tonsillectomy, poliomyelitis is especially likely to take the bulbar form and that not only the site but also the incidence and severity of paralysis may be affected by prophylactic inoculations. In patients with paralytic poliomyelitis muscle weakness has been observed in limbs that had sustained trauma. This paper gives the histories of five patients in whom trauma preceded the appearance of paralytic poliomyelitis by a few days. These five cases were found in a review of the records of 100 cases, and in each of the five cases paralysis appeared in muscles closely related to the site of trauma. Possible factors in the production of this paralysis are briefly discussed.

*Treatment of Chronic and Relapsing Tonsillitis with Roentgen Rays. M. de Jong.—p. 1137.
Bacteroides Infections. H. Beeuwkes, J. B. M. Vismans and A. H. Smeets.—p. 1143.
*Importance of Bronchi in Primary Pulmonary Tuberculosis. G. M. H. Veeneklaas.—p. 1153.

Roentgen Irradiation in Tonsillitis.—Roentgen irradiation was employed in 60 patients with chronic or relapsing tonsillitis. On the first day, following anesthesia with a tetracaine (pontocaine®) hydrochloride spray contact irradiation was given on a field measuring 20 by 28 mm. Dosage per tonsil was 400 r. The tube was directed so that the entire tonsil was in the ray field. Externally the rays were applied to a field 8 by 8 cm. with a focus-skin distance of 40 cm., with a tension of 180 kv., and with a 0.5 mm. copper filter. Both tonsils were irradiated on the same day. The dosage on the skin (measured in air) was 150 r. On the third day the two external fields were irradiated as on the first day. On the fifth day the procedure was again as on the first day. All patients were reexamined from two to three years later. Thirty patients were cured, and 22 were greatly improved. Tonsillectomy became necessary in 12 of the patients, but in nine of these the roentgen irradiation had not been completed. The author recommends a wider application of irradiation in chronic tonsillitis.

Involvement of Bronchi in Pulmonary Tuberculosis.—Primary pulmonary tuberculosis is considered as chiefly located in the lungs. The importance of the bronchi in this disease receives slight attention. Reports in the literature, theoretic considerations, and his own observations convinced Veeneklaas that the bronchi are probably involved in the majority of cases of primary pulmonary tuberculosis and that pulmonary shadows are generally the result of bronchial lesions. Rupture of lymph nodes into the bronchi is more frequent than is suspected.

*Treatment of Tetanus with Large Doses of Refined Tetanus Antitoxin Globulins. H. Verhagen.—p. 1247.

Tetanus Therapy with Large Doses of Refined Tetanus Antitoxin Globulin.—According to some observers, the length of the incubation period is the decisive factor in the prognosis of tetanus; that is, if it is seven days or less, tetanus is nearly always fatal, whereas if it is longer than nine or 10 days, a large percentage of recoveries can be obtained by serum therapy. Verhagen believes that the type of antitoxin is also vitally important and describes his experiences with a refined tetanus antitoxin globulin containing much less protein than do other antitoxin preparations and with a much greater (10 fold) concentration of antitoxin (10,000 units per cubic centimeter). This makes it possible to administer much greater quantities of antitoxin in a smaller amount of fluid and with fewer foreign proteins. The author describes the histories of three patients who recovered following the use of this antitoxin. Their incubation periods were 12, seven, and eight days, respectively. The initial doses of refined antitoxin administered intravenously to these three patients were 200,000, 100,000, and 150,000 units, respectively. Smaller doses of the refined antitoxin were given after intervals of several days.

Artificial Myxedema During Paraaminosalicylic Acid Administration. K. H. Clausen and K. Kjerulf-Jensen.—p. 475.

Meperidine-Nitrous Oxide Anesthesia Without Barbiturate Supplement.—In 59 cases from the surgical division of the Finsen Institute, mostly in elderly patients regarded as poor risks, nitrous oxide anesthesia supplemented by meperidine (pethidine) hydrochloride was employed. The average duration of the operation was three hours. Ruben and Andreassen found that with this combination anesthesia there was little or no impairment of normal function. The urinary output was sufficient, and intestinal peristalsis was active throughout the anesthesia. The compensatory mechanism of the circulatory system functioned well. The patients regained consciousness before they left the operating table and were surprisingly little affected by the anesthesia. Of the three deaths none was attributable to the anesthesia.

Carcinomatous Meningitis. O. B. Ramse.—p. 517.
Subscapular Muscle Graft According to Magnuson in Recurrent Dislocation of Shoulder. B. Köhler.—p. 519.

Cancer Focus.—Bang concludes that cancer starts as a local affection, which, if left to itself, becomes universal. The primary cancerous tumor or ulceration with degeneration is designated as a cancer focus. In experimental tar cancer three phases are distinguished. In the preparatory phase the tissue changes are reversible. In the preinvasive or latent phase a latent cancer focus has formed and the tissue changes are irreparable; the tissue has become anatomically and physiologically disorganized, and the cells divide abnormally. In the invasive phase the cancer cells have suddenly attained the faculty of invasive growth. Growth impulses, possibly in the form of hormonal influence, appear to be important in the development of cancer, and absence of these may be the reason that latent foci occasionally do not develop. It is suggested that the faculty of invasive growth may depend on an increase in virulence of a viruslike factor, formed in the dividing cells during the preceding phase.

Gastric Acid Phosphatases in the Diagnosis of Cancer.—After determining the acid phosphatase content of gastric secretions in 26 fasting patients, seven of whom had cancer of the stomach, Rønnike concludes that the arbitrary limit of 10 units of phosphatase per 100 cc. of secretion cannot be used to distinguish between the cancerous and noncancerous stomach. Eighteen of the 19 patients in this series without cancer showed phosphatase values higher than 10. In many cases the values were far above those reported by Changus and Dunlap. There was no demonstrable relation between the pH of the stomach contents and the phosphatase values. The phosphatase test was of no apparent value in the diagnosis of cancer of the stomach in this group.

*BCG Vaccination as Means of Combating Tuberculosis. H. Scholer.—p. 383.
Triad of Diaphragmatic Hernia—Diverticulosis—Cholelithiasis. B. Wissmer.—p. 396.

BCG Vaccination.—Experience with BCG vaccination performed on five million to ten million persons over a period of 20 yr. in various European countries, particularly in the Scandinavian countries, suggests that this procedure may be safely recommended, subject to the following considerations: (1) BCG vaccination is permissible only in persons who have not been affected by tuberculosis and (2) it is imperative in persons who have been heavily exposed to tuberculosis and are approaching an age at which they are particularly sensitive to tuberculosis. Persons who have passed through natural primary infection should not be vaccinated. Vaccination is most indicated for small children and nursing infants in a hazardous environment, boys and girls nearing puberty who at the same time are leaving the paternal home, and tuberculin-negative medical and veterinary students and nurses. The greatest disadvantage of the BCG vaccination is its cumbersomeness. The author believes that the application of a living BCG suspension of 75 mg. per cubic centimeter to the skin followed by puncture of the subjacent skin may provide a simplified and improved allergy indicator and may result in simultaneous vaccination of those with negative reactions (Ustvedt's test modified by Delachaux and Bergier). No observers report the occurrence of any general untoward reactions. It may be assumed that tests with living BCG suspension are innocuous in carriers of a manifest or latent allergy (carriers of a primary infection). In those cases in which there is no positive reaction with the occurrence of red nodules after 24 to 72 hr. (early reaction), BCG vaccination by intracutaneous administration of 0.05 to 0.10 mg. of BCG vaccine could be performed easily. It may be assumed that repeated BCG vaccination will be innocuous and may increase the protection provided; it may even prevent or tend to prevent tertiary tuberculosis. The protection period provided by BCG vaccination has not yet been fully determined, but reliable protection should be assumed after two to four months. There are reports on the duration of the tuberculin allergy after vaccination, but this allergy is not identical with immunity. BCG vaccination is the best available prophylactic, and it should not be discredited by uncautious procedures.

Value and Mechanism of Antidotal Action of Sodium Tetrathionate in Hydrocyanic Poisoning. L. Binet, G. Wellers and J. Dubrisay.—p. 641.
*Qualitative and Statistical Comparison of Symptomatology of Gastric and Duodenal Ulcers. P. Chêne, J. M. Gorse and A. Eyrolle.—p. 643.
Encephalographic Study of Acromegaly. E. Garcia Austt Jr. and J. C. Mussio Fournier.—p. 645.

Clinical Aspects of Gastric and Duodenal Ulcers.—Of 1,400 cases of peptic ulcer, 1,200 occurred on the duodenal bulb and 200 on the lesser curvature, i. e., a ratio of 1 to 6. This incidence suggested the possibility of the existence of two different diseases, despite double localization in about 10% of the cases. From the analysis of the 1,400 cases were excluded the rare cases of ulcer of the bulb in patients between the ages of 13 and 17, those with double localization, those associated with gallbladder involvement, and cases of ulcer of the pylorus. Of the 1,400 peptic ulcers, 16% were in women and 84% in men. Of the ulcers on the lesser curvature, 64.2% were in men and 35.8% in women, while 92.1% of the ulcers on the duodenal bulb were in men and 7.9% in women. All but 2.5% of the patients with duodenal ulcer (Bucquoy's disease) showed the classic course of the functional disturbance and the characteristic symptoms, thus proving that the clinical picture is remarkably fixed. However, 47.5% of the patients with ulcer on the lesser curvature (Cruveilhier's disease) had attacks of pain that were atypical in their rhythm of appearance and in their quality. This makes the clinical diagnosis of gastric ulcer more difficult than that of duodenal ulcer. The authors disagree with the classic view that postprandial pain occurs very late in duodenal ulcer and somewhat earlier in gastric ulcer. The concept that ulcer on the duodenal bulb and ulcer on the lesser curvature may be two diseases is supported by the following facts: giant duodenal ulcers are rare, but large ulcers occur quite frequently in the stomach; large gastric ulcers may disappear and cicatrize completely, while regression takes place infrequently in duodenal ulcer; patients with duodenal ulcer rarely regain their normal weight after gastrectomy, while patients with gastric ulcer do so rather rapidly. Thus gastrectomy does not seem to have the same effect on both conditions. It is suggested that ulcer on the lesser curvature may be a more "local" disease than ulcer on the duodenal bulb.

*Surgical Treatment of Hypertension. J. Ramos, E. J. Zerbini, S. Dos Santos Carvalhal and others.—p. 183.
*Hemolytic Disease of the Newborn: Considerations of 12 Cases Treated with Exchange Transfusion. O. Mellone, C. da Silva Lacaz and O. Yahn.—p. 251.

Surgical Therapy in Arterial Hypertension.—Ramos and collaborators performed thoracolumbar sympathectomy by either Smithwick's or Grimson's technique in 56 patients with arterial hypertension. A biopsy of the kidney and of the intercostal muscle was made during operation in 31 cases. The authors describe the technique of the operations and the histopathological aspects of the renal and intercostal muscular lesions encountered. They believe that the operation is indicated whenever the clinical treatment of hypertension fails and in cases of hypertensive heart disease with cardiac insufficiency. The patients of this report were followed for three months to three years after sympathectomy. Three of 56 patients died within the first month after the operation (operative mortality rate, 5.3%). Immediate satisfactory results on blood pressure and the subjective and objective clinical symptoms were obtained in 50% of the cases. The roentgenologic and electrocardiographic evidence of left ventricular hypertrophy disappeared. However, in half of these patients blood pressure increased within one or two years to near or above preoperative figures, and the electrocardiographic changes reappeared. In six patients with hypertensive cardiac disease with cardiac insufficiency, good cardiac compensation was obtained, which was maintained for more than two and a half years. The good results of sympathectomy in arterial hypertension are probably due to the effect of the operation in lowering the vascular lability of the patients. The operation is of value mainly because it temporarily suppresses the subjective and objective symptoms of the disease and prolongs comfortable life of the patients.

Hemolytic Disease of the Newborn.—The authors report the results obtained in 12 newborn infants who had exchange transfusion therapy for hemolytic disease due to maternal-fetal Rh incompatibility. Sensitization of the mother to the Rh factor was due to multiparity in five cases and to the administration of Rh-positive blood transfusion to the mother in previous pregnancies in four cases. Good results were obtained in eight cases in which exchange transfusion was performed early. One thousand cubic centimeters of blood were injected and 900 cc. were withdrawn. Four patients died because of delayed treatment.

*Early and Late Congenital Syphilis: Study of Its Treatment. R. Debré, M. Lamy, P. Mozziconacci and J. Labesse.—p. 1321.
Anatomicoclinical Study of Bronchial Embolism in Nursing Infants. R. Debré, R. Grumbach and J. Caron.—p. 1337.
Periosteal Dysplasia or Porak and Durant's Disease. R. Debré, P. Mozziconacci, R. Grumbach and C. Attal.—p. 1345.

Treatment of Congenital Syphilis.—Of 4,055 nursing infants admitted to the Children's Hospital from January, 1941, to July, 1950, only 32 had congenital syphilis, indicating the rarity of the disease. This report covers 104 cases of congenital syphilis, 63 in children less than 1 yr. old, 13 in children between 1 and 2 yr., and 28 in children between 2 and 14. Twenty-five children died, 23 of them less than one year old. The disease is severe in younger infants because of the resultant debility and the high incidence of secondary infections. The authors believe that congenital syphilis may be prevented in 75% of the cases, provided that routine serologic tests are done during pregnancy and at least immediately before delivery and penicillin treatment practiced properly in mothers with a positive reaction to prenatal tests. Complete clinical recovery resulted from treatment with penicillin in 30 infants aged less than 2 yr. who were followed for four years, since not one of them had late secondary or tertiary syphilis. Seven of 24 infants treated with arsenic and heavy metals before the age of 2 yr. had clinical relapses, with hemiplegia in two. Treatment with arsenic and heavy metals is nearly always inadequately practiced. The only inconvenience associated with the use of penicillin is the Herxheimer reaction, which cannot yet be prevented. Only three children between the ages of 2 and 14 were treated with penicillin; the results obtained with the antibiotic were no better than those obtained with other antisyphilitic treatment. After a follow-up of five years positive serologic reactions had turned negative in only one case. Hospitalized nursing infants with congenital syphilis should be treated for 15 days with daily doses of about 10,000 units of penicillin G per kilogram of body weight, administered in three-hour injections. A vehicle that delays absorption of the antibiotic may be preferred for ambulatory treatment. The extremely low dose of 1 unit of penicillin per kilogram of body weight is recommended as the daily dose for the first three days of treatment in nursing infants with severe diffuse, congenital syphilis in an attempt to prevent the Herxheimer reaction. Treatment with 1,000,000 units of penicillin daily for 15 days is adequate for cure of cutaneous and osseous manifestations in older children. It should be combined with fever therapy in neurosyphilis.

*Injuries with Loss of Finger Tips: Repair and Results. F. Lengemann. —p. 551.

Cervical Sympathetic Block in Cerebral Concussion.—Blocking of the cervical sympathetic chain by procaine hydrochloride is a truly causal therapeutic method, because it promptly counteracts the spasm of the cerebral vessels, greatly reduces the tendency to further spasms, and, by producing hyperemia, prevents cerebral edema or facilitates the resorption of existing edema. The pathological process in cerebral concussion is usually at first purely spastic and therefore reversible, and treatment should be performed during this stage before the process has become irreversible and before cerebral vasomotor irritability has developed, which sometimes causes belated headaches and dizziness. The author refutes the charge that cervical sympathetic block is dangerous, pointing out that he and his collaborators encountered no unavoidable serious complications in over 500 blocks. Hypersensitivity to procaine hydrochloride is possible, but this causes only minor disturbances. Strict adherence to an exact technique of injection will prevent complications. The author does not agree with those who wish to replace cervical sympathetic block with stellate ganglion block, since the technique of the latter is more difficult and dangerous and the effect of the cervical sympathetic block is more extensive. He is not, however, completely opposed to blocking of the stellate ganglion but uses it only when there is involvement of the upper extremities and thoracic organs. Block of the cervical sympathetic should be performed with the patient either sitting or on his side. The needle is introduced at the posterior edge of the sternocleidomastoid at the level of the fifth or sixth cervical vertebra. The head should be turned toward the healthy side; turning the face toward the opposite side can be dangerous. In 67 of 103 cases a single block was done, and in the remaining 36 cases it had to be repeated once or twice.

Injuries with Loss of Finger Tips: Repair and Results.—Lengemann reviews observations on 60 persons who sustained injuries causing loss of finger tips. He shows that conservative methods are adequate only when tissue loss is slight and the end of the phalanx is covered by an adequate layer of tissue. If the terminal phalanx or the stump lies open, plastic repair is advisable. The author mentions various methods that are available for this purpose and says that he obtained the best results with a sliding graft described by the Lahey Clinic in 1945.

BOOK REVIEWS

The Kidney: Structure and Function in Health and Disease. By Homer W. Smith, A.B., Sc.D., M.S., Professor of Physiology, New York University College of Medicine, New York. Cloth. $12.50. Pp. 1049, with 153 illustrations. Oxford University Press, 114 Fifth Ave., New York 11, 1951.

The plethora of current medical publications tends to obscure the fact that there are published occasionally volumes of superlative merit, literally modern medical classics. Such a volume is this extraordinary monograph on renal physiology, in which both the regulatory and excretory functions of the kidney are considered in painstaking detail. It is difficult to imagine any pertinent fact that has been omitted. Only an investigator with a lifetime of research in renal physiology could successfully undertake so monumental a task; no living physiologist is better equipped than is Homer Smith.

This volume is no book for the casual professional reader, nor is it intended for the pragmatic clinician who desires bedside rules of thumb. Indeed, in the preface, the author warns that current methods of study of renal physiology may be too elaborate for general clinical application. It is, rather, a comprehensive dissertation of renal function, as far as current knowledge makes possible, for the investigator, the teacher, and the advanced student of renal physiology.

Following the brief historical introduction, the text is divided into four sections. Part I contains chapters on renal anatomy and, in considerable detail, the methods of measuring renal function, particularly the clearance methods, by which our present understanding of function has been attained. Part II includes chapters on the antidiuretic hormone and the excretion of water, the excretion of sodium and other strong electrolytes, the adrenal cortex and Addison's disease, and acid-base equilibrium in plasma and urine. Part III consists of chapters on the control of the renal circulation and the action of pharmacodynamic agents, trophic and other factors related to renal function, renal function in infancy and childhood, the comparative physiology of the kidney, and renal hemodynamics. The final section is devoted to the alterations of renal physiology that occur in disease. It is introduced by a discussion of the limitations of the clearance methods during disturbed renal function. Disturbances of renal function are then discussed under the following headings: primary disturbances of salt and water balance, altered function in nonrenal disease, chronic congestive heart failure, essential hypertension, and acute renal failure related to toxic and traumatic injuries. Additional chapters on the juxtamedullary circulation, diseases of the kidney and urinary tract, and diuretics complete the section.

The illustrations are for the most part charts and graphs demonstrating data obtained experimentally. The comprehensive bibliography contains no less than 2,300 entries referred to in the text.

This volume, while it can be read profitably in a series of sittings, is primarily a reference work covering all phases of renal physiology. The details of experimental findings tend to become monotonous despite the author's careful subdivision of the text. Such a criticism might not be held by one who is concerned exclusively with the experimental approach. The volume does not compete with Addis's "Glomerular Nephritis," with Oliver's "Architecture of the Kidney," or with Bell's "Renal Diseases." Rather, it belongs on the reference shelf by the side of these volumes.

An Introduction to Universal Serologic Reaction in Health and Disease. By Reuben L. Kahn, D.Sc. Cloth. $3.50. Pp. 159, with 113 illustrations. Commonwealth Fund, 41 E. 57th St., New York 22; Oxford University Press, Amen House, Warwick Sq., London, E.C.4, 1951.

In this monograph Dr. Kahn gives an account about his investigations on serologic reactions with lipid antigen. It is an important collaborative study originated as an attempt to prove "that the reaction between tissue extract antigen and serum might not be primarily a syphilis reaction." It is based on "an inherent biologic tendency for serum to react with antigen—a tendency which is unrelated to syphilis." By using a multiple quantitative precipitation system each of a different sodium chloride concentration, Dr. Kahn found that all human beings and many animals give positive precipitation reactions "differentiated from one another by serologic patterns which are based on the degree and arrangement of precipitation" in the various reacting zones. Therefore, the term "universal serologic reaction" appears justified. Various diseases other than syphilis (tuberculosis, yaws, leprosy, malaria) showed definite changes in serologic patterns.

The volume is clearly written by a distinguished author of high reputation. Its purpose is not to present the principles and technics of serology applied to the diagnosis of syphilis, but to inspire the study of "universal serologic reaction" in various diseases. The lucid exposition of the complex subject is to be commended.

Clinical Heart Disease. By Samuel A. Levine, M.D., F.A.C.P., Clinical Professor of Medicine, Harvard Medical School, Boston. Fourth edition. Cloth. $7.75. Pp. 556, with 192 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, 1951.

As in the earlier editions, the new volume has for its purpose the presentation in a simple form of the important aspects of the diagnosis, prognosis, and treatment of heart disease. Despite its modest claim there is much of value and interest for the cardiologist as well as the general practitioner. The need for the new edition is more than justified by the rapid and dramatic advances in the diagnosis and treatment of heart disease. Within recent years the field of cardiology has been broadened by the introduction of new methods of investigation, such as catheterization of the heart, and by studies in unipolar and precordial leads in electrocardiography. The therapeutic possibilities in the treatment, particularly of congenital heart disease, have been enlarged by introduction of a number of surgical interventions. Previously, the mortality rate for bacterial endocarditis was 100%; use of antibiotics now effects cure in 75% of cases. The discussion is authoritative, lucid, and adequate. Much new material brings it up to date. This is particularly true of the discussion of the subject of electrocardiography. The volume is a valuable contribution to the subject of cardiology.

Problems of Infancy and Childhood: Transactions of the Fourth Conference, March 6-7, 1950, New York, N. Y. Edited by Milton J. E. Senn, M.D. Cloth. $2.50. Pp. 181. Josiah Macy, Jr. Foundation, 565 Park Ave., New York 21, 1951.

This book provides a verbatim transcript of three papers dealing with the development of behavior patterns and of personality, along with the attendant discussion. The titles and authors of the papers are "Cultural Determination of Parental Attitudes: the Relationship Between the Social Structure, Particularly Family Structure and Parental Behavior," by George Peter Murdoch and John W. M. Whiting; "A Consideration of Some Problems in the Ontogeny of Family Life and Social Adjustments in Various Infra-Human Animals," by T. C. Schneirla, and "Working Toward Healthy Personality," by Laurence K. Frank. The essayists and those who participated in the discussion are highly skilled experts from the fields of the social sciences and the medical specialties. Although each paper might be considered independently from the others, for the purpose of this review the substance of the conference may be considered best as a whole.

Personality was considered to relate to various factors: biologic factors (based on inheritance and the physiologic status at birth); training and example (principally from the mother and other close associates, its nature determined by their cultural backgrounds); sibling rivalries, and discrimination and prejudice from associates. Through anthropologic studies, comment was made pertaining to the manner in which commonplace events may modify behavior patterns either favorably or unfavorably:

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

these include the course of breast feeding, weaning techniques, toilet training, aggression control, development of independence, and sex training. These elements of care were compared under different types of social organization and of family unit. From animal behavior studies, evidence was offered with respect to the modifiability of what usually are termed "instinctive" behavior patterns through the imposition of external forces.

The need for general concern pertaining to the promotion of mental hygiene was emphasized as a proper corollary to efforts in preventive medicine and pediatrics. Those working with children should learn to identify the major threats and hazards to the emerging personality and detect those persons who are especially susceptible to environmental handicaps. The inefficacy of fear or a sense of guilt as motivators for desirable child behavior was stressed. It is important to give the young child a sense of confidence in his own abilities as a basis for his emotional security. One must help him develop a favorable self-image; if he can have self-approbation, it will favor a desirable pattern of response. There are periods that are especially critical in the determination of personality attributes: these are periods of stress, such as the time of weaning, of toilet training, of starting school, and of other breaks from the immediate family circle, and the appearance of puberty. Such breaks with the past patterns permit reorientation, and at such times favorable changes can be brought about through proper motivation. The more prompt the relief from unfavorable environmental patterns, however, the better the outlook for the achievement of an acceptable personality. There are preferred techniques to employ at each period of the child's unfolding personality if one is to incur the least risk of damage or distortion, or of permanent, persistent infantilism.

This small volume contains much valuable food for thought for all who deal directly or indirectly with the child. The material is well written, and the typography is excellent. It is recommended especially for the pediatrician, the obstetrician, and the psychiatrist; it should be of equal value to the general practitioner of medicine.

Introduction to Statistical Analysis. By Wilfrid J. Dixon, Associate Professor of Mathematics, University of Oregon, Eugene, and Frank J. Massey, Jr., Assistant Professor of Mathematics, University of Oregon. Cloth. $4.50. Pp. 370, with illustrations. McGraw-Hill Book Company, Inc., 330 W. 42d St., New York 18; Aldwych House, Aldwych, London, W.C.2, 1951.

This book is an introduction to statistical analysis in a rather unusual way. Most introductions take up the simpler subjects, while this text stresses tests of significance, the more advanced aspect of statistics. It is an introduction in the sense that it is a summary of statistical method and a description of the material that would be obtained from a complete discussion of the subject. The book presents all the common statistical tests of significance and the associated confidence limits. It omits algebraic proof in all cases. Empirical checks on sampling distributions are described and illustrated, and they constitute what the authors choose to call statistical proof. The book provides excellent illustrations of these significance tests and should be very useful as a reference source for the research worker. Their illustrations are chosen from a variety of fields, and they state explicitly that general statistical methods should be applicable equally in most fields of research.

The reader should be warned that the authors use one rather uncommon approach. They give extreme emphasis to the concept of degrees of freedom even apart from the problems of sampling. This can be most easily understood by an example. On page 20 the authors define variance as the sum of the squares of the deviations of the observations from the mean divided by one less than the total number of observations. This is easily recognized as an estimate of population variance obtained from the sample. It is highly irregular to call it the variance of the sample. It is regrettable that the authors choose to do so in conflict with almost all recognized usage. This causes considerable difficulty in later description. For example, on page 39 they are forced to give an excuse for a variance calculation when the denominator is N, the entire number in the universe. This would not have arisen if they had defined variance in the usual way and had restricted the division by the number of degrees of freedom to the standard terminology "estimate of population variance." This confusion also led them astray in their discussion of regression in Chapter 11. The line fitted by least squares must be obtained without the use of degrees of freedom if the sum of the squares of the vertical deviations is to be minimized. In this instance the numerical description which they give on pages 155 and 156 is incorrect in the denominators, and the nonmathematical reader will be badly confused if this text is used in conjunction with the standard textbooks on statistics.

Aside from this difficulty, this book is well written and is a valuable addition to the library of any research worker. It is regrettable that the authors choose to confuse the reader by defining estimates of population parameters as being the parameters themselves when discussing them in respect to a sample drawn from the population.

Remington's Practice of Pharmacy: A Treatise on the Preparing, Standardizing, and Dispensing of Official, Unofficial, and Extemporaneous Pharmaceutical Products, with Descriptions of Medicinal Substances, Their Properties, Uses and Doses. Also a Guide to Other Professional Services Rendered by the Pharmacist in Connection with Community Health. Intended for the Use of Pharmacists and Physicians and as a Textbook for Students. By E. Fullerton Cook, P.D., Ph.M., D.Sc., Chairman of Committee of Revision of Pharmacopeia of United States of America from 1920 to 1950, Philadelphia, and Eric W. Martin, Ph.C., B.Sc., Ph.D., Associate Director of LaWall and Harrisson, Philadelphia. With collaboration of more than ninety associates. Tenth edition. Cloth. $16. Pp. 1616, with 802 illustrations. Mack Publishing Company, 20th and Northampton Sts., Easton, Pa., 1951.

The periodical appearance of this useful book is always of great interest to practicing physicians, pharmacists, and members of the allied professions. First edited in 1885 by Joseph Price Remington primarily as a handbook for students of pharmacy, it has kept pace in its successive editions with the kindred sciences of medicine, chemistry, and pharmacy. The present edition is almost of encyclopedic proportions.

The text has been divided by the editors into fifteen distinct parts, including a history of pharmacy and a chapter on research in pharmacy. As in previous volumes, one part of the text is devoted to the various official and important unofficial preparations in commonest use. Various classes of drugs are reviewed in separate chapters; thus included are chapters on vitamins, hormones, amino acids, enzymes, sulfonamides, and antibiotics, as well as certain portions of the texts of "United States Pharmacopeia" (fourteenth edition), "National Formulary" (ninth edition), and "New and Nonofficial Remedies—1950."

The inclusion of statements indicating the therapeutic actions and doses of drugs, a novel feature of the ninth edition, has been carried over into the present volume. A comprehensive index makes for ready reference and adds materially to the usefulness of the book. This edition is a complete refresher course for pharmacists and contains much of value to the physician.

Perception: An Approach to Personality. By Robert R. Blake, Associate Professor of Psychology, University of Texas, Austin, and Glenn V. Ramsey, Professor of Psychology, University of Texas, in collaboration with Frank A. Beach, and others. Cloth. $6. Pp. 442, with 39 illustrations. The Ronald Press Company, 15 E. 26th St., New York 10, 1951.

This book is comprised of 13 papers which were delivered at the 1949-1950 Clinical Psychology Symposium held at the University of Texas. The symposium received financial support from a grant awarded by the National Institute of Mental Health of the United States Public Health Service. The book is intended for use in upper level courses in perception, personality, and experimental and social psychology. The view presented is that study of perceptual activity can provide a basic approach to personality and interpersonal relations. In an attempt to achieve continuity and integration in this material, each author was provided with an outline of the theoretical framework of the symposium at the start of the project and was given an opportunity to familiarize himself with the contributions of other authors before making his own contribution.

After a general orientation in the perceptual approach to personality, the book discusses the physical and chemical determinants of perception, the social and developmental factors that influence perceptual activities, and the role of perceptual constructs in unconscious processes and in psychotherapy.

A comprehensive index of authors and subjects has been added as a means of quick reference to the many separate investigations cited in the book.

Physical Education: Organization and Administration. By J. B. Nash, Ph.D., Professor of Education, New York University, School of Education, New York, Francis J. Moench, Ph.D., Director of Education, Division of Health, Cortland College of Education, State University of New York, New York, and Jeannette B. Saurborn, Ph.D., Director of Physical Education, Elementary School, Bronxville, New York. Cloth. $5. Pp. 498, with 61 illustrations. *A. S. Barnes and Company, 101 5th Ave., New York 3, 1951.*

Because of the increasing interest in therapeutic exercise on the part of physicians in general, medical practitioners are showing increasing interest in physical education. Drs. Nash, Moench, and Saurborn are well qualified to discuss the organizational and administrative aspects of this subject. This new general textbook covers these phases of physical education thoroughly and authoritatively. The book is divided into eight parts: introduction, selecting objectives, setting the stage, routine administration, evaluating outcomes, elementary school program, secondary school program, and special problems.

While this basic textbook on teaching procedures in physical education will be of only secondary interest to most physicians, it will be found to be a complete and thoroughgoing dissertation concerning the development and proper conduct of teaching programs, particularly in elementary and secondary schools.

Somatic Development of Adolescent Boys: A Study of the Growth of Boys During the Second Decade of Life. By Herbert Rowell Stolz, M.D., and Lois Meek Stolz, Ph.D. Cloth. $9. Pp. 557, with illustrations. The Macmillan Company, 60 Fifth Ave., New York 11, 1951.

This volume presents observations recorded by the California Adolescent Study undertaken jointly by the Institute of Child Welfare of the University of California, and the public schools of Oakland, Calif. The purpose of the seven year research program was to present a longitudinal study of adolescents. The book includes a wealth of data on somatic and social development collected on the same persons in the course of semiannual physical examinations and by observations made in the classroom, during recreation, and in the home. Included also are a number of serial photographic records and a detailed account of one of the subjects to show how personal-social relations may bear a close relation to the timing and configuration of somatic growth patterns. Emphasis throughout the book is placed on the broader scope of the "longitudinal" studies of children as compared with the older, cross-sectional type of study. This book should be of value to pediatricians, psychologists, educators, and all others interested in child development.

Social Aspects of Illness. By Carol H. Cooley, Director of Social Service, Presbyterian Hospital, Chicago. With foreword by Edna S. Newman, M.A., R.N. Cloth. $3.25. Pp. 305. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, 1951.

This is a book on the social work aspects of illness prepared for use in nursing education. "Social factors" in illness are defined rather broadly, including, for example, climate and environmental factors. For the most part, the book deals with emotional, economic, familial, and community factors affecting the patient and his care. The book should be valuable in giving nurses better insight into the types of problems that a social worker tries to handle and some of the methods used. It is scarcely specific enough to enable the nurse to handle such problems alone, even to the extent that might be expected of nurses with some training in the social work aspects of illness.

Personal Health and Community Hygiene. By Harold S. Diehl, M.A., M.D., Sc.D., Professor of Preventive Medicine and Public Health, University of Minnesota, *Minneapolis, and Ruth E. Boynton,* M.S., M.D., Professor of Preventive Medicine and Public Health, University of Minnesota. Second edition of Healthful Living for Nurses. Cloth. $4.50. Pp. 469, with 38 illustrations. McGraw-Hill Book Company, Inc., 330 W. 42d st., New York 18; Aldwych House, Aldwych, London, W.C.2, 1951.

This is a greatly augmented and improved as well as revised edition of the textbook first issued under this title in 1944. The authors bring to it their broad experience with healthy as well as sick persons, to produce a fully rounded, well-organized, expensively documented, and, at the same time, interestingly written textbook for nurses. The discussion suggestions that follow each chapter and the references and reading suggestions recommend the book highly to teachers in training schools for nurses. The book is well illustrated with pictographs, drawings, charts, and tables. It covers the entire scope of personal and community health, including quackery, cultism, health in school and on the job, and the role of government in public health, with a glimpse into the future. Particularly valuable are the chapters on sex life and on the diseases of advancing age. This book can be recommended without reservation as a basic textbook or as a useful reference volume.

Factors Regulating Blood Pressure: Transactions of the Fourth Conference, February 23-24, 1950, New York, N. Y. Edited by Benjamin W. Zweifach and Ephraim Shorr. Cloth. $3. Pp. 219, with 39 illustrations. *Josiah Macy, Jr. Foundation, 565 Park Ave., New York 21, 1951.*

The purpose of the book is to present in only slightly edited form the presentations and discussion of a small group of very competent students of blood pressure. The coverage is broad and includes such topics as anatomical considerations, clinical criteria for diagnosis, renal changes, relationship of adrenal glands, arteritis of dietary origin, vasoexcitor and depressor materials, treatment of experimental renal hypertension with renin, purification of angiotonin, and measurement of the renin content of kidneys.

The beginner in the field would be completely baffled by the contradictions and inadequacies in logic that characterize all such informal conferences. Those more skilled in the topic and familiar with the personalities involved will find this volume a delight and heartily to be recommended, as are the three precedent companion volumes. They represent science in the raw before winnowing and logical rearrangement have changed its color and texture. Whether this is good or bad depends on one's taste for raw meat and one's ability to digest it.

The material is too varied and uneven for specific criticism. Only one point in editing must be noted in the hope that it can be corrected before it is too late. This is the repeated use of terms such as Goldblatt animals, Schroeder syndrome, Van Slyke-Phillip dogs, Goldblatt mechanisms, and other such noninforming eponyms. The book is well printed, cheap and altogether desirable if a blow by blow description of the changing scene of research is wanted.

El lactante vomitador (visto por el cirujano): Estudio crítico, diagnóstico etiológico, tratamiento consecuente. Por Emilio Roviralta, *cirujano* ortopédico y de los niños de los Institutos policlínico y neurológico de Barcelona. Cloth. Pp. 299, with 75 illustrations. José Janés, editor, Muntaner, 316, Barcelona, 1950.

The clinical aspects of vomiting of suckling babies is the subject of a thorough analysis of this interesting monograph. The author exhausts every phase of this clinical entity and discusses fallacious concepts of the subject matter. He presents a clear-cut plan for the study of the subject. The work is of value to the general practitioner, the surgeon, and the pediatrician. The book is divided into 24 chapters, in which every phase of the condition is lucidly entered into and thoroughly described, and will act as a guide to the reader, outlining the etiology, symptomatology, and therapy clearly and comprehensively. The radiologic examinations in these conditions, which frequently lead to diagnostic errors, form an outstanding chapter, which is ably presented. The book is of particular value in differential diagnosis. A comprehensive index concludes the work. Those reading Spanish and those who are interested in the subject will find it of value.

Tratamiento quirúrgico de las varices esenciales. Por Víctor Salleras y Ramón Brull. Prólogo del Prof. J. Puig Sureda. Cloth. Pp. 250, with 118 illustrations. José Janés, editor, Muntaner, 316, Barcelona, 1950.

This monograph is an excellent, up-to-date presentation of the subject. The first part deals with the history of the development of the surgical procedures to treat the principal forms of varicosities.

The book is divided into 12 chapters: history, etiology, diagnosis and indications; treatment; surgery; combined treatment; anatomical aspects; surgical technique; postoperative complications; essential complications; varicose ulcers, and varicophlebitis and recurrent varices. Every aspect of the subject matter is discussed. Photographs, charts, line drawings, and excellent radiographs augment the text. For those who read Spanish, the book will prove of value. Particularly since the knowledge of varicosities and their complications have recently given an impetus for study and great advances have been recorded, this book should be instructive.

QUERIES AND MINOR NOTES

SPINAL PUNCTURES AND HEAD INJURIES

To the Editor:—*What is the opinion regarding the routine use of spinal tap, with or without manometer readings, in all cases of head injuries regardless of other findings?*

Philip Von Hunger, M.D., Escalon, Calif.

Answer.—Any condition that varies as widely as do the clinical manifestations of injuries to the head cannot be treated in routine fashion. It is as ridiculous to state that one should routinely use spinal punctures in case of injuries to the head as it is to state that one should never use them. There are times when spinal punctures like many other procedures can be of value, both diagnostically and therapeutically, in cases of this type. There are various situations in which one would decide to make a spinal puncture, and one would particularly do so in considering the diagnosis of infectious meningitis, to relieve the symptoms of a traumatic subarachnoid hemorrhage or to measure the pressure of the cerebrospinal fluid. On the other hand, there are certain situations in which a spinal puncture would generally be ill advised, as in cases in which there was severely increased intracranial pressure, particularly if the pressure had persisted and had given rise to choking of the optic disks. One would not generally make a spinal puncture in cases in which there was a discharge of cerebrospinal fluid from the nose or ears, or in which there was a compound wound of the scalp with an opening into the intracranial cavity.

DRUG ADDICTION

To the Editor:—*A man, 50, has been taking about 700 mg. of meperidine hydrochloride (demerol®) and 80 mg. of methadone hydrochloride (dolophine) daily for one year. Drugs were prescribed for pain from a spinal tumor, which was removed eight weeks ago, and the pain has disappeared, but now the drug addiction is obvious. I note that the literature advises the use of methadone in treatment of morphine addiction. In this case, with the patient already taking methadone, do you think it possible or advisable to stop the meperidine, replace it with additional methadone, and then, with the patient taking only methadone, gradually reduce the methadone? I would greatly appreciate advice as to the feasibility of this plan.*

M.D., New York.

Answer.—Methadone can be substituted for meperidine in addicted persons without signs of abstinence appearing. The procedure proposed in the question would be the preferred method of withdrawal of meperidine. Probably no more than 100 mg. of methadone daily would be required. Since the patient is recovering from a long illness, reduction should be done rather slowly, and about 30 days should elapse before methadone is completely discontinued.

RETROLENTAL FIBROPLASIA IN TRIPLETS

To the Editor:—*The principal of a school for the blind has just related to me a case of triplets in all three of whom occurred retrolental fibroplasia. He feels this is the only recorded instance of this kind. Can you confirm this?*

Arthur A. Rodriquez, M.D., Chicago.

Answer.—The occurrence of retrolental fibroplasia in all three triplets has not been reported in the literature. There is, however, a relatively high incidence of retrolental fibroplasia among twins and triplets because multiple pregnancies frequently terminate prematurely and retrolental fibroplasia occurs almost exclusively among prematurely born infants. Among 421 patients with retrolental fibroplasia who have been seen at the Columbia-Presbyterian Medical Center, for example, there were 54 sets of twins (normal expectancy 4.5 sets) and seven sets of triplets (normal expectancy 0.056 sets). Among the twins only one infant survived in each of 24 sets. Of the remaining 30 sets, both infants had retrolental fibroplasia in 15 cases and only one was affected in the remaining 15. Among the seven sets of triplets all three infants survived in five cases. In two of these, two of the infants had retrolental fibroplasia and one was normal, and in three cases one was affected and two were normal. In both of the remaining two cases of triplets one infant died and the surviving infants developed retrolental fibroplasia. There is suggestive evidence that in monozygotic twin pregnancies either both or neither twin is affected, whereas in dizygotic twin pregnancies retrolental fibroplasia may develop in one twin independently of the other (Speert, H.; Blodi, F. C., and Reese, A. B.: *Am. J. Obst. & Gynec.* **59**:246, 1950).

DIET FOLLOWING GASTRECTOMY

To the Editor:—*Please advise me on the postoperative care of a gastrectomy patient, especially in regard to diet.*

Nathan Mann, M.D., Corpus Christi, Texas.

Answer.—The patient, after gastrectomy, should be kept on appropriate intravenous feeding for one or more days. Complete rest of the gastrointestinal tract for a few days after operation tends to reduce the incidence of digestive disturbances when oral intake is started. If an indwelling tube is in the stomach, the appropriate time for starting oral feeding is shown by a change from bile-stained to clear fluid, a diminution in the amount of aspirated gastric contents and absence of retention when a trial drink of 200 cc. is given with the tube clamped. Once motility is restored, the diet should be rapidly increased from simple liquids to a full diet, including milk and solid food. If the gastrectomy is done for peptic ulcer, the objective of the operation is to obviate the need for ulcer diets and the patient should therefore be so told and instructed to eat well of anything he likes (aside from rich, greasy and highly spiced foods). He should also be told that there is often a short transitional period, lasting a few days to a few weeks, during which the gastrointestinal tract becomes adjusted to the new anatomic arrangement. During this period it is usually advisable for the patient to eat small amounts frequently, particularly if but a small amount of stomach remains.

BLEEDING FROM NASOPHARYNX

To the Editor:—*A 44 year old man has had slight bleeding from the nasopharynx for two years. He has a history of hay fever. Examination of the nasopharynx discloses a brownish bloody discharge on the right side, from the region above the posterior tip of the inferior turbinate, but the site of origin cannot be seen. Other results of examination were normal except for some hypertrophy of the nasal mucosa. Two biopsies of the area of bleeding disclosed no abnormalities. Sinus x-rays were normal. What further measures should be taken in regard to diagnosis and treatment?*

M.D., Illinois.

Answer.—In the event they have not been employed during examination of the nasopharynx, the nasopharyngoscope and the pharyngoscope may well be used, especially since effective treatment depends on establishment of an accurate diagnosis. Cystic degeneration of the seromucinous glands in the nasopharynx should be considered and a cytological and chemical analysis of the bloody discharge made. The condition could be due to low grade infection of the mucosal lining of a persistent nasopharyngeal bursa, an entity known as Thornwaldt's disease, which is not infrequently accompanied by a slight amount of bleeding. Treatment of Thornwaldt's disease involves destruction of the lining mucosa of the bursa by means of a silver nitrate stick, trichloracetic acid or electrodesiccation.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

SCREENING SCHOOL CHILDREN FOR VISUAL ERRORS

To the Editor:—*Among public health personnel there is a controversy over the relative merits of the Snellen chart (for illiterates) and the Massachusetts vision-testing apparatus for screening school children for refractive errors. Is the Massachusetts vision-testing method superior, and do its advantages compensate for the extra investment of money and time necessary for its application?* *M.D., Michigan.*

Answer.—The Massachusetts vision test is an important step forward in that, in addition to the Snellen test, which screens out myopia and all other defects which impair vision (and which is an integral part of the Massachusetts vision test), it includes a simple but effective and inexpensive test for hypermetropia of + 1.75 D or over and for significant amounts of heterophoria which do not affect vision and does it in a simple and less expensive way than the tests advertised by several commercial houses.

The Snellen test alone fails to screen out a good many cases needing care. The Massachusetts and similar tests pick up many of these (as is highly desirable). They include also a moderate number of children who do not need glasses. This is unavoidable. It must be understood that the child is referred to the specialist without any diagnosis or hint given as to what the school test revealed—only that the test showed that there were grounds for suspecting that treatment was needed.

Those who are in charge must be painstakingly trained to deal with the parents so tactfully and wisely that they will feel it is a privilege of great value to have their children shown to be healthy and normal and to have this proof that the school is alert and sparing no pains to make sure that their children will not suffer from neglect. Also these parents should be made to realize that the methods of school examination, in order to detect the defective children, must inevitably subject some normal ones to the inconvenience and expense of an examination by an expert.

RHEUMATOID ARTHRITIS AND PREGNANCY

To the Editor:—*A 58 year old woman has had rheumatoid arthritis, without limitation of motion of any joint, for 38 years. Her condition has been diagnosed by many internists. She became worse during each of two pregnancies. She has had every treatment, up to the most recent, without success. I started treatment with desoxycorticosterone acetate, 5 mg. intramuscularly, and ascorbic acid, 1,000 mg. intravenously. Her pains became worse, and her temperature increased a degree for two or three days after each injection. X-rays show typical rheumatoid arthritis, but results of physical examination for arthritis are entirely normal. She has frequent bouts of arthritic pain not relieved by the usual drugs. What would you suggest?*

F. M. Logsdon, M.D., Marfa, Texas.

Answer.—Assuming that the diagnosis is correct as stated, it seems necessary, nevertheless, to indicate that the diagnosis may need to be reviewed. The inquirer states that the patient shows no limitation of motion in any joint and that results of physical examination for arthritis are entirely normal. This is certainly unusual for a patient who has had rheumatoid arthritis for 38 years. Absence of physical findings for so long suggests the possibility that the patient may have been suffering from fibrositis. If the diagnosis of rheumatoid arthritis is correct, it is necessary to comment on the statement that symptoms have been aggravated during pregnancy. In at least 85 per cent of cases the opposite effect is observed. Symptoms of rheumatoid arthritis are relieved by pregnancy. Occasionally, however, symptoms may not be notably relieved, and in rare instances aggravation of symptoms may occur in pregnancy for unknown reasons. This patient's experiences during pregnancy cannot, therefore, be used to support or refute the diagnosis as given. Experiences with desoxycorticosterone acetate in association with ascorbic acid as a treatment measure for rheumatoid arthritis have repeatedly proved unsatisfactory, and in some instances this therapy can aggravate symptoms rather than relieve them. If hormone therapy is to be undertaken for this patient, it would seem more reasonable that one use cortisone and follow dosage plans outlined in published papers (Hench, P. S.; Kendall, E. C.; Slocumb, C. H., and Polley, H. F.: Effects of Cortisone Acetate and Pituitary ACTH on Rheumatoid Arthritis, Rheumatic Fever, and Certain Other Conditions, *Arch. Int. Med.* 85:545 [April] 1950; Boland, E. W., and Headley, N. E.: Management of Rheumatoid Arthritis with Smaller (Maintenance) Doses of Cortisone Acetate, *J. A. M. A.* 144:365 [Sept. 30] 1950; Rosenberg, E. F.: Rheumatoid Arthritis Therapy with Pituitary Adrenocorticotropin, Cortisone, and Various Adrenal Steroids, *M. Clin. North America* 35:3 [Jan.] 1951).

FREQUENT URINATION IN SIBLINGS

To the Editor:—*I have observed three members of one family, two males, ages 46 and 40, and one female, aged 33, all of whom have had urgency and frequency of urination since puberty. All three have been examined, and all findings are negative for genitourinary pathology. Is it possible that in all three there is a congenital or familial psychoneurogenic bladder? No gross or apparent psychological or emotional problems have been uncovered in any of them. What would you suggest?*

L. A. Cibelli, M.D., New York.

Answer.—The incidence of urgency and frequency of urination since puberty in three members of one family without apparent etiologic organic lesions is unusual. Urinary frequency in the female may be caused by lesions that may be difficult to detect on casual clinical examination. Interstitial cystitis with little or no cystoscopic evidence, chronic urethritis with moderate pathological changes in the urethra, infection of urethral and periurethral glands, obscure urethrocele and various other lesions may be easily overlooked by urinalysis and by cystoscopic or urethroscopic examination. In the male, chronic verumontanitis with or without prostatitis and vesiculitis may cause frequent urination without evidence of infection in the urinary tract revealed by casual examination. If any of these conditions exist, dilatation of the urethra followed by local medication usually relieves the symptoms. It may be well to try such treatment empirically even if clinical evidence of organic lesions is lacking.

Patients are sometimes observed, however, who have a tendency to urinate more frequently than average in the absence of any organic lesion in the urogenital tract. It would be logical to infer that such symptoms may be of a functional type. Such persons may have hypersensitive innervation of bladder control, which causes them to respond to the slightest stimuli. This tendency has been observed in several members of the same family and could be explained best on a psychoneurogenic basis. In the absence of any specific medication for such patients, there are several antispasmodic drugs that might be tried. In some cases frequent micturition has been reduced by alkalinization of the urine. The possibility of allergy could be considered, although an uninterrupted persistence of symptoms since puberty would make it doubtful.

BROMIDE IN THE BLOOD SERUM

To the Editor:—*What is the bromide level in the blood during bromide intoxication? I can find no literature on this subject and would greatly appreciate this data.*

A. Del Giudice, M.D., Binghamton, N. Y.

Answer.—Wikoff and his colleagues (*J. Lab. & Clin. Med.* 24:427, 1939), as quoted by Kolmer (Clinical Diagnosis by Laboratory Examinations, ed. 2, New York, Appleton-Century-Crofts, Inc., 1949), reported that the normal bromide of the blood serum varies from 0.33 to 1.73 mg. per 100 cc. A blood bromide concentration of 150 mg. per cubic centimeter is considered the upper limit of safety and amounts above 150 mg. are usually accompanied by signs of intoxication. However, some patients may tolerate concentrations as high as 200 mg. per cubic centimeter. It is not uncommon to find, in patients who have been taking bromides for a long time and have bromoderma, a concentration of 75 to 100 mg. per cubic centimeter or more.

INCOMPLETE RIGHT BUNDLE BRANCH BLOCK

To the Editor:—*I examined a 6 year old boy last summer and noted a systolic murmur; other findings were negative. The heart had been normal eight months previously. There had been minor intervening illnesses of the upper respiratory type, but nothing indicating rheumatic fever. An electrocardiogram showed an incomplete right bundle branch block and no evidence of rheumatic carditis, and a recheck showed similar findings. The child has been symptom free and has had no complaints. The electrocardiogram taken four months later showed incomplete right bundle branch block with a conversion of the T waves in leads V_2 and V_3 from an inverted position to an upright position, but no evidence of rheumatic fever. An x-ray of the chest showed some suggestion of mitral disease. I would appreciate a discussion of the significance of these electrocardiographic findings.*

Norman L. Schmitt, M.D., Detroit.

Answer.—The diagnosis of incomplete right bundle branch block may be difficult. Similar changes may result from right ventricular hypertrophy. The two conditions may coexist. When the QRS is 0.09-0.11 second in duration and S_1 prominent in the standard leads, V leads should be recorded. A late R^1 in V_{1-2} following the initial small R spike usually indicates incomplete right bundle branch block. In view of the history and findings, a diagnosis of active rheumatic carditis is not justified. The conduction disturbance may be of congenital origin. An old, healed, unrecognized lesion of rheumatic or other origin could be responsible. Treatment should be expectant. Discussion of the problem with the parents should be guarded.

GASTRIC ULCER IN AN INFANT

To the Editor:—*I referred a newborn child to a pediatrician because the baby was not doing well. Nothing specific could be found, but the child did not gain and appeared pale. The pediatrician, after several weeks, gave a diagnosis of gastric ulcer. I have never seen, or read of, gastric ulcer in the newborn. Please comment.*

Herbert B. Potthoff, M.D., Winslow, Ariz.

Answer.—Gastric and duodenal ulcers were once considered rare in infancy and early childhood, but many instances were probably overlooked in the past. In one third or more of the reported cases, ulcers have been found at autopsy of infants and children dying of other causes. Ulcers in the duodenum are said to be 10 times as frequent as those occurring in the stomach, and 70 per cent of the reported cases of duodenal ulcer have been observed between the ages of 6 weeks and 5 months; 10 per cent of the duodenal ulcers occur in the newborn. Hemorrhage is the only symptom of duodenal ulcer, and the blood may be either vomited or passed in the stool.

Two reports on gastric and duodenal ulcer in infancy appeared in the December 1950 issue of the *Journal of Pediatrics:* "Bleeding Duodenal Ulcer in Infancy: A Surgical Problem," by George W. Plummer and Samuel J. Stabins, and "Perforated Gastric Ulcer in a Newborn Infant," by Lydia T. Wright and Beatrice E. Scott.

PYROGENS AND ESSENTIAL HYPERTENSION

To the Editor:—*Can you give me any information on essential hypertension with fever therapy?*

Roger C. Smith, M.D., New Haven, Ind.

Answer.—Several reports have appeared concerning the therapeutic effects of intravenous injection of bacterial pyrogens. These soluble glucosides are bacterial products which are carefully removed from fluids prepared for intravenous infusion to avoid febrile reactions. Page and Taylor, reporting in modern concepts of cardiovascular disease, used pyromen,® a soluble pyrogen marketed by Baxter Laboratories, and stated that they administered a daily intravenous injection for five to six days per week, starting with 0.5 cc. of the solution and modifying the dose until temperatures of 103 F. to 104 F. were consistently obtained. These authors state that it is important to limit the application of this method to patients with good renal function.

Essentially, the intravenous application of soluble bacterial pyrogens in the therapy of hypertensive disease is still in the stage of clinical experimentation. Fever is a violent systemic reaction, affecting the hydration of tissues, and may thus initiate undesirable as well as desirable changes in the tissues, both vascular and parenchymal. It has been reported that fever therapy caused papilledema to disappear from the retinas of patients with malignant hypertension, but this does not prove that damage may not have been done elsewhere. In the management of early benign, so-called essential, hypertension one must remember that these patients feel well, are normally vigorous and energetic and often resent the implication that they are ill. Therefore, any therapy requiring frequent injections and/or discomfort, such as a violent febrile reaction, will rarely be persisted in unless the patient is excessively apprehensive. It is most important not to add to anxiety. Thus it appears doubtful that pyrogen therapy will be a significant addition to the therapeutic armamentarium in hypertensive disease other than for the late malignant form.

INDUCED ADRENAL ATROPHY

To the Editor:—*Are there records of any carefully made postmortem studies of the pituitary and adrenals in patients with chronic rheumatoid arthritis not treated with hormones and patients treated for long periods with pituitary adrenocorticotropic hormone (ACTH) or cortisone? Will life be shortened by cortex atrophy if the patient is given replacement therapy with cortisone or by pituitary damage and premature adrenal exhaustion if pituitary adrenocorticotropic hormone is given?*

M.D., New York.

Answer.—To date, there is no evidence that the atrophy of the adrenal induced by cortisone therapy or the hyperactivity induced by pituitary adrenocorticotropic hormone results in any permanent disturbance in adrenal function after treatment has been withdrawn. Functional studies carried out by a number of investigators revealed the restoration to normal of hormonal activity following the withdrawal of these agents.

ARSENIC AND DIMERCAPROL

To the Editor:—*A 63 year old woman was admitted to the hospital claiming to have taken arsenic. She received 4.5 cc. of dimercaprol (BAL) immediately and 2.5 cc. every four hours thereafter. She died on the fifth day, after a total dosage of 36 cc. Autopsy revealed acute ulcers in the stomach and throughout the colon and degenerative changes in the liver. Toxicological studies of the brain, liver and kidneys were negative for the heavy metals, in particular, arsenic. Could the dimercaprol therapy prevent the identification of arsenic, or other poison, in the tissues?*

N. H. Stoer, M.D., Shreveport, La.

Answer.—Arsenic, had it been present in the tissues of the deceased person, would have been detected by any of the commonly employed quantitative toxicological procedures. It is not difficult to establish the presence of as little as 1 microgram per 100 Gm. of tissue by means of the relatively simple Gutzeit test, for example. The presence of dimercaprol would not affect the detection of arsenic by any procedure in which the tissues are completely destroyed by wet or dry ashing. Since arsenic was not detected postmortem, the question arises as to whether it could have been the cause of the ulceration of the gastrointestinal tract and the degenerative changes in the liver and kidneys. In the absence of further information it will be assumed that these changes were of recent origin and that the alleged ingestion of arsenic occurred shortly before admission to the hospital. Although dimercaprol may enhance the urinary excretion of arsenic in the human being, it appears unlikely that it could do so to such an extent as to prevent its chemical detection after five days, particularly if the amount of arsenic ingested were sufficient to be acutely toxic and ultimately fatal. It appears that urinary arsenic determination during hospitalization would have been an important aid in evaluation of the validity of the diagnosis and in the determination of the efficacy of the treatment.

VITAMINS

To the Editor:—*A woman has been taking a vitamin concentrate daily for several years and claims to feel better while taking it. She is in the menopause and is also taking one of the estrogens daily. Recently she developed acute pain in the back, and x-rays show osteoarthritis in the lumbar and sacral region. She has always taken about a quart of milk a day. Is this vitamin concentrate contraindicated? Would it be better to give the patient a vitamin B preparation? Hemoglobin and blood cell count are normal. The patient leads a very active life. She wears firm support for the back. I would appreciate further suggestions.* *M.D., New York.*

Answer.—There is no reason to believe that the vitamin concentrate taken by this patient is in any way related to the osteoarthritis of her spine. This type of arthritis at her time of life is extremely common, and it is probably, in the last analysis, an expression of the wear and tear of life. Whether a patient who is properly nourished and has no impairment of her alimentary tract, as is apparently true of this patient, should take a polyvitamin mixture throughout the years is questionable. The quart of milk a day is proper and should not in itself contraindicate the vitamins. Regarding the thiamine, no specific need is apparent; if the physician wishes, there would be no harm in his giving 10 mg. of thiamine hydrochloride by mouth in tablet form three times daily for a limited period, perhaps two or three months. The importance of a balanced diet should be emphasized. The patient should learn that, for the maintenance of robust health, vitamins should as a rule be obtained from the food.

ELECTRICAL POTENTIALS IN DEATH

To the Editor:—*What is the usual sequence of disappearance of electrical potentials in the dying human, e. g., brain wave activity and electrocardiographic activity? If this has not been studied in humans, has it been worked out for animals?* *M.D., Utah.*

Answer.—If death is due to failure of the heartbeat, the electrocardiographic activity disappears before the electrical activity of the cortex (electroencephalogram), but, if death is due to respiratory failure or to a gradual circulatory failure, the electroencephalographic activity usually disappears before the electrocardographic. The cortex is much more sensitive than the heart to lack of oxygen and to hypoglycemia.

Sometimes, after the heart has failed and both types of activity have entirely disappeared, recovery of the heartbeat may occur. The electrocardiogram is a sensitive indicator of such recovery. After a few heartbeats, as evidenced in the electrocardiogram, the electrical activity of the brain may revive. This can occur, however, only if the nutrition of the brain (oxygen and glucose supply) has not been impaired too seriously for too long.

Most of the information on this subject has been obtained from animal studies, but Dr. Robert Schwab, of the Massachusetts General Hospital, has studied the electrocardiographic and the electroencephalographic activity prior to and during death in a human being (The Measurement of Body Currents, *Amer. Inst. of Electrical Engineers* **60:** 1941).

TUBERCULOUS ARTHRITIS

To the Editor:—*A patient has tuberculous arthritis of the right wrist with subcutaneous abscesses. May streptomycin be given intra-arterially? What dilutions and dosages would be appropriate? Have any beneficial effects been reported from such treatment of tuberculous arthritis?* *S. D. Austin, M.D., Clarksdale, Miss.*

Answer.—Streptomycin apparently has not been used intra-arterially, and it would be most difficult to continue such a method of administration. The ordinary intramuscular method will answer the purpose. The dosage should be about 1 Gm. a day for 60 to 90 days, or longer if the wound is still unhealed but continues to progress favorably. Damage to the eighth nerve may be suspected if any vertigo or similar symptoms appear.

Administration of 12 Gm. of paraaminosalicylic acid daily would be much more rational, and the streptomycin doses should be spaced further apart. It is common practice now to give two doses a week of streptomycin, and daily doses of paraaminosalicylic acid. The paraaminosalicylic acid is given four times a day, in water, near meal time, so as to protect against the irritant action on the stomach. It is better to give the sodium salt, which is available at all the large drug houses. Many authorities prescribe dihydrostreptomycin instead of streptomycin. This drug seems to be slightly less neurotoxic, and dosage up to 1.5 Gm. a day may be given. While the streptomycin and dihydrostreptomycin are usually given in intervals ranging from 45 to 90 days, paraaminosalicylic acid may be continued for several months if improvement continues.

SMALL GENITALIA

To the Editor:—*A 30 year old man, in good health, weight 155 pounds (70 Kg.) and 5 feet 10 inches (178 cm.), is apparently normal except for the size of his genitalia. His penis in erection is about 4½ inches (11.4 cm.) long and about 4½ inches (10.75 cm.) in circumference. His testicles and scrotum are small. Orgasm in intercourse takes an unduly long time. I gave him a seven week course of A. P. L.® (chorionic gonadotropin preparation), 500 to 750 units, three times weekly. No noticeable change took place. I then followed with intramuscular injections of testosterone propionate, 25 to 37.5 mg. three times weekly for six weeks, and no change in sex organs has taken place. His basal metabolic rate, ascertained before these treatments were begun, is —5. Kindly advise the therapy indicated.* *M.D., New York.*

Answer.—If the sexual organs of this man were atrophic because of a deficiency of male hormone, substitution therapy with testosterone would restore the organs to their normal size. Since this patient had no response from adequate replacement therapy, it can be deduced that the size of his sexual organs are normal from an endocrine standpoint, and no further growth can be obtained beyond this stage. The small size of the genitalia is apparently a genetic characteristic, and any distress he may have because of this should be corrected as much as possible by reassurance and elimination of doubts as to his sexual potency.

SHAVING THE SCALP

To the Editor:—*Is there any scientific truth to the repeated observation that shaving the scalp causes hair to curl? Shaving the scalp is usually recommended after recovery from an acute infectious disease. If the hair curls, is it due to the fever, or to the shaving, or is it another fallacy?* *M.D., Indiana.*

Answer.—There is no scientific evidence to support the contention that shaving the scalp causes the hair to curl. It is also rumored, but not confirmed by controlled observations, that roentgen epilation of the scalp will result in the hair's being curly when it grows back. There is no scientific support for the belief that shaving the scalp or prolonged fever will produce curly hair.

MAINTAINING COLLAPSE IN TUBERCULOUS CASES

To the Editor:—*Mineral oil has been used extensively as oleothorax to maintain a permanent or semipermanent collapse in tuberculous cases. Is there any evidence that mineral oil as used in these cases predisposes to malignant change?* *M.D., Missouri.*

Answer.—There is no evidence that liquid petrolatum (mineral oil) predisposes to cancer when used to maintain a semipermanent collapse of the lung in tuberculosis. Occasionally there will be a foreign body reaction on the tissue surface approximating the oil, but nothing more serious than this has been reported. To obviate any possibility of cancer due to coal tar products, one might use poppy seed oil, which is less irritating.

PRINCIPLES FOR IMPROVING PATIENT CARE IN THE HOSPITAL LABOR AND DELIVERY SUITE

Edwin M. Gold, M.D., Jere B. Faison, M.D., Helen M. Wallace, M.D.
and
Margaret A. Losty, R.N., New York

If one views the picture of maternity care broadly, there are two areas that are of greatest importance to the life of the expectant mother and the fetus: (1) the antepartum period and (2) the period during labor and delivery. A blueprint for antepartum care has already been briefly described.[1] This report will describe many of the essential features of care during labor and delivery that are necessary to protect the life and promote the well-being of the expectant mother, the fetus, and the newborn. These features are described as a result of surveys of the 106 hospitals in New York City having maternity and newborn services. The surveys were conducted by members of consultant survey teams of the maternity and newborn division of the New York City Department of Health.

OBSTETRIC SUPERVISION

It would be expected that the maternity service, of which the labor and delivery suite is part, should be under the direct medical supervision of a qualified obstetrician. Such an obstetric director should be responsible for the establishment of the technical obstetric policies and procedures for the care of patients during labor and delivery. Daily rounds would be made by the director, or by an obstetrician or staff of obstetricians, to provide the necessary supervision so that the established policies and procedures would be well carried out.

Of major import to the expectant mother and her fetus are policies regarding the indications that warrant consultation with a qualified obstetrician. Such consultation indications usually include the following: major obstetric operative procedures; forceps delivery other than outlet forceps; serious obstetric or medical complications, such as toxemia, bleeding, cardiac disease, premature labor, diabetes, and the like; breech presentation, and labor of more than 24 hr. in primiparous patients. The question of the need of consultation for multiparous patients with breech presentation is in the process of being studied.

In addition to adequate obstetric supervision at the attending staff level, there should be adequate obstetric house staff coverage, which serves two functions: (1) the training of interns and residents in obstetrics and (2) the provision of continuous medical supervision of the patient during labor and delivery. Ideally, every maternity service should be of such caliber as to be approved for the training of interns and residents in the specialty and therefore should be of the type that will ensure eligibility for the American Board of Obstetrics and Gynecology for house staff members who participate in the full residency system of training. Since the great bulk of obstetrics throughout the country is performed by physicians in general practice, there should also be adequate opportunity for the training of these future practitioners. Delineation of functions of the attending, resident, and intern staff is necessary if there is to be adequate protection for the patient in labor and during delivery.

It is desirable that the physicians who give antepartum care to patients in the hospital's antepartum clinic be members of the hospital's inpatient staff so that there will be continuity of medical care of the patient.

ANESTHESIA SERVICE

It is a curious dichotomy in the pattern of medical practice that there is a discrepancy in the quality of anesthesia service for the surgical operating room and for the delivery suite. In these hospitals that have well-organized anesthesia departments, it is not uncommon to find anesthesia service being rendered to surgical patients by well-trained and qualified physician and nurse anesthetists; in contrast, the anesthesia service for

---

A qualified obstetrician is herein described as one who holds any one or combination of the following ranks: (1) specialist certified by the American Board of Obstetrics and Gynecology, (2) fellow of the American College of Surgeons (in the specialty of obstetrics and gynecology), and (3) associate attending obstetrician or higher at a voluntary or municipal hospital.

[1] Gold, E. M.; Wallace, H. M., and Losty, M. A.: A Blueprint for Changing Concepts of Antepartum Care, Am. J. Pub. Health 40: 792-797 (July) 1950.

the delivery suite is usually of a "pick-up" nature—anyone may render such anesthesia. This survey finding is reflected in the fact that in New York City anesthesia has now emerged as one of the major causes of maternal mortality, being outranked only by hemorrhage, infection, heart disease, and toxemia.[2] This dichotomy becomes even more marked when it is realized that there are usually at least two lives at risk in the delivery room (mother and fetus), while only one life is at risk in the surgical operating room.

It follows then that each hospital having maternity service should have available at all times a well-organized anesthesia department, part of whose functions is the provision of anesthesia service to those obstetric patients who are to receive it. Either well-trained and qualified physician or nurse anesthetists may be used. Such personnel will also play a major role in the determination of feeding policies during labor and of resuscitation of the newborn.

NURSING STAFF

It is generally agreed that the nursing care of the patient in labor and during delivery is one of the strategic areas of patient care in any hospital. Just as there is a qualified obstetrician responsible for the medical supervision of patients in labor and delivery, so too there should be a well-qualified nurse in charge of the labor and delivery suite. Such a member of the nursing staff should have had advanced preparation in the field of maternity nursing and should be directly responsible to the nursing supervisor of the maternity service. There should be a staff of registered professional nurses for each tour of duty in sufficient numbers to provide or supervise good patient care. The number will depend on the size of the maternity service and the number of deliveries to be done.

There have been no studies undertaken to indicate what sized nursing staff is necessary for patients in labor and during delivery nor any studies to indicate the proper proportion between the nursing staff at the registered professional nurse level and the nursing staff at the level of practical nurses, aides, attendants, and the like. It is, however, generally agreed that labor patients, particularly those who receive analgesia, should not at any time be left unattended. It is likewise agreed that there should be one member of the nursing staff, and preferably two, functioning in the delivery room during a delivery. If the labor and delivery suite has a recovery room, an adequate nursing staff must be provided in this area if the purpose for which the recovery room is intended is to be served.[3]

The personnel of the labor and delivery suite will depend to a certain extent on whether there is a central supply room in the hospital, or whether the making and sterilization of supplies for labor and delivery are done in the delivery room suite itself. The former arrangement is more efficient and economical. The latter requires additional nursing supervisory and auxiliary personnel, as well as space in the labor and delivery suite, and furthermore requires so careful a definition of duties in this area, that the time of the registered professional nurse, who is essential for good patient care, is not spent in washing gloves, making supplies, and the like. Such duties constitute a waste of skill and training.

PHYSICAL SETUP

The physical setup of a labor and delivery suite may be functionally divided into the following areas: (1) areas of patient care, including admission room, labor room, delivery rooms, and recovery room; (2) areas for staff functions, including physicians' dressing room, nurses' dressing room, office of the obstetric director, office of the nurse in charge, office for the anesthetist, chart room or area, and scrub-up, and (3) accessory facilities, including obstetric cleanup, nurses' workroom, sterilization room (if a central supply room is not provided), laboratory, storage, and utility room.

AREAS OF PATIENT CARE

Admission Room.—It is essential that the labor unit contain an admission room, where the new labor patient may be received into the unit, and where the admission history and physical examination may be performed. Here too the patient may be bathed and prepared for labor and delivery.

Labor Rooms.—The number of labor rooms and delivery rooms will depend on the number of maternity reservations made for a given period and on the amount of patient turnover in the maternity service. A practical index to use is the provision of one labor bed for each 10 postpartum beds. In order to provide patient privacy, each labor patient should be in a separate room. Each single room should have a minimum of 80 sq. ft. of floor space and have hot and cold running water equipped with arm, foot, or knee control, sphygmomanometer, stethoscope and the like. All equipment for the patient, such as a thermometer and bedpan, should be at the bedside. All labor beds should be equipped with sideboards to protect the patient.

Delivery Rooms.—A practical index to use in the planning of delivery rooms is one delivery room for every 20 postpartum beds. A minimum of two delivery rooms is essential in any service, for there are occasions when it is necessary to conduct more than one delivery at a time. At no time should there be two deliveries conducted in the same room at the same time. Each delivery room should be provided with adequate supplies and equipment for the protection of the life of the mother and her newborn infant, including an anesthesia machine, delivery instruments, medications, a cutdown set, a supply of plasma and intravenous fluids, a modern thermostatically controlled incubator or heated crib that should be kept warm at all times, resuscitation equipment for the newborn infant, identification equipment, and oxygen. Obviously, there must be personnel at each delivery well versed in the art of resuscitation of the newborn infant. It is desirable that a small amount of blood, both Rh positive and Rh negative of all four types, be kept in the delivery suite for emergency use, since hemorrhage is the major cause of maternal mortality in New York City at present. Adequate lighting is essential, as well as provisions for the prevention of electrostatic hazards.[4] Many hospital authorities consider it desirable to soundproof and air-condition the labor rooms and the delivery rooms. If cesarean sections are to be performed in the delivery suite, one delivery room should be completely equipped as an operating room. If, on the other hand, cesarean sections are performed in an operating room, the operating room should be equipped to receive and give immediate care to the newborn infant.

---

[3] McLean, L. F.; McDowell, H. C., and Sadugor, M. S.: The Use of the Recovery Room in Lowering Meternal Mortality, New York State J. Med. 48: 1368-1370 (June 15) 1948.

Recovery Room.—If there is sufficient nursing staff available, a recovery room is an additional safeguard for the patient in order to observe and evaluate her condition more fully before her transfer to the postpartum service.

Areas for Staff Functions.—Such areas should include, near the entrance to the labor and delivery unit, separate facilities where physicians and nurses can change their clothes; in addition, shower and toilet facilities for each group are necessary. Offices should be provided for the obstetric director, the nurse in charge, and the anesthetist. A chart room or area is essential if there is to be adequate recording of the patient's progress in labor and during delivery. It is obvious that adequate scrub-up facilities are necessary, preferably with direct vision into the delivery rooms.

Accessory Facilities.—Accessory facilities should include an obstetric cleanup room, where used supplies and equipment may be taken after a delivery and immediate cleaning performed. If a central supply room is not provided in the hospital, the labor and delivery unit should have its own workroom and sterilization room. Storage areas are essential. The labor unit should have a utility room, equipped to perform sterilization of bedpans, enema equipment, and the like. It is desirable that the labor and delivery unit have a small laboratory equipped to perform an admission urinalysis, emergency blood typing, cross-matching, and Rh determination.

Other Necessary Hospital Services.—As is true in the care of all hospital patients, certain other hospital services are necessary for the care of maternity patients and newborn infants. For example, the hospital should be expected to provide a general laboratory department under the immediate direction of a qualified pathologist and with an adequate and trained laboratory technician staff at all times. Such a laboratory should be able to perform bacteriological, biochemical, hemotological, and pathological determinations.

Another important general hospital service that is necessary is the x-ray department under the immediate direction of a qualified roentgenologist and with an adequate and trained x-ray technician staff at all times. Such a department should be able to perform x-ray pelvimetry according to one of the accepted techniques.

RECORDS

Adequate records of labor and delivery are important if the obstetric director is to be able to evaluate patient care. A continuous and current labor and delivery record book is essential. This record book should contain basic information regarding the identification of the patient, parity, length of labor, type of delivery, type of anesthesia, name of physician performing the delivery and name of consultant if any, name of anesthetist, and condition of fetus or newborn infant, including birth weight. Such data should be summarized monthly and then annually.

Each patient's record should contain information regarding her antepartum care; course during labor, delivery, and the period immediately after delivery; laboratory data, and consultation notes. If the patient attended the hospital's antepartum clinic, her clinic record should be available immediately on her entrance to the labor unit. If she is a private patient, her physician should be expected to send a résumé of her antepartum care to the hospital's labor and delivery unit shortly before the expected date of confinement.

The record of the newborn infant should be initially filled out in the delivery room and should include the essential data regarding the mother as well as initial condition in the delivery room.

STATISTICAL EVALUATION AND STAFF EDUCATION

If improvement in patient care is to be made, there should be opportunity for periodic review of current care. One method by which this objective may be accomplished is the institution of periodic joint staff meetings of the obstetric, pediatric, pathology, and nursing staffs, to discuss problems within the service and to review maternal, fetal, and neonatal mortality and morbidity. This system should be of great educational value to all personnel concerned with the care of maternity patients and newborn infants.

SUMMARY

This report describes some of the essential features of a labor and delivery suite of a hospital maternity service, suggested by members of a hospital consultation service, as a result of surveys of hospitals in a large metropolitan area. The suggestions include obstetric supervision, anesthesia service, nursing supervision and staff, physical setup and equipment, other necessary hospital services, records, statistical evaluation, and staff education.

[4] Recommended Safe Practice For Hospital Operating Rooms, National Fire Protection Association, Boston, 1949.

Infant Feeding.—Nature produced breast milk in the mother to feed the infant for the greater part of the first year. The first teeth do not erupt before six or seven months because nature did not anticipate any need for them. Ptyalin does not appear in the saliva in appreciable amount before the third or fourth month of life. The infant does not learn to use his tongue and jaws to attempt to chew and mix and swallow solid foods before he is three and one-half or four months of age. The intestinal tract is unable to filter out large protein molecules from the food before the child is six or eight months of age. . . . There have been an endless number of various food modifications for infant feeding. None has ever surpassed or ever equaled breast milk as produced by nature. The best substitute for breast milk is a properly prepared cow's milk modified to the approximate composition of human breast milk.—M. G. Peterman, M.D., So-Called "Progress" in Infant Feeding, *Rocky Mountain Medical Journal*, June, 1951.

PRINCIPLES AND FACILITIES FOR THE CARE OF NEWBORN INFANTS IN THE HOSPITAL

Lawrence B. Slobody, M.D.
and
Helen M. Wallace, M.D., New York

In this postwar era of hospital planning, construction and reconstruction, considerable thought and money have gone into the various hospital services. Nationally, interest in the standards of newborn care has been expressed by several groups,[1] and has, of course, been stimulated by the federal Hospital Survey and Construction Act. The pediatrician must actively participate in planning the newborn service.

PEDIATRIC CARE

The service for newborn infants should be under the direct supervision of the pediatric staff of the hospital; this principle has been adopted in many of the teaching hospitals in this country and should be extended to all hospitals. As a corollary of this principle, a qualified pediatrician, usually the director of the pediatric service, should be the director of the newborn service. He should have the responsibility for the establishment of the technical pediatric policies and procedures and for the supervision of the newborn service, so that such policies and procedures are carried out. Daily rounds on this service should be made by the director or by a staff of one or more attending pediatricians appointed by the director.

There should be pediatric house-staff coverage throughout the entire 24-hr. period. The pediatric house staff assigned to the newborn service should have no duties, during such assignment, in the care of sick infants and children on the general pediatric service but it might simultaneously be assigned to the premature center, to the well baby clinic and to the special premature follow-up clinic, if any or all of these services are provided in the hospital. House-staff duties during this period should include assignment to the delivery room for the immediate care of the newborn infant, and possibly also to the antepartum clinic of the hospital, since in these areas the pediatrician can play an important role in patient care. Patterns established in the antepartum and immediate postpartum periods play a vital role in the development of proper parent-child relationships.

The continuous review of care already given infants is an important educational tool in the improvement of such care. One form of educational activity is the periodic pediatric staff meeting, held jointly with members of the obstetric, pathologic and nursing staffs, to review mortality and morbidity. Such a plan necessitates inclusion of one or more members of the pathology department who are interested and trained in the field of neonatal pathology. It also provides for keeping current statistics for the service, including total deliveries, live births,—under and over 5½ lb. (2.5 kg.)—deaths by causes, and infants alive at the time of discharge. Such analysis might be carried further to include a breakdown by color and by type of patient, whether on private or general service.

There is, too, a responsibility for assisting parents in making plans for the continuing medical supervision of the infant after discharge from the hospital, whether such care is to be given by a private physician, hospital well baby clinic or by a community well baby clinic.

NURSING STAFF

The service for the newborn should be under the direct supervision of a registered professional nurse[2] who has had advanced training in all phases of newborn care. She should continue the training of the various persons comprising the nursing and auxiliary staff who care for newborn infants. In addition, experience has shown that there is a close parallelism between the provision of a capable, well-trained nursing supervisor and the quality of patient care rendered on the newborn service. To provide supervision of patient care over the 24-hr. period, there should also be on each shift a head nurse with advanced training in this special field.

For the direct care of the newborn there should be one nurse for every eight full-term newborn infants at all times. Observations have led us to believe that there is little or no significant difference in the amount of nursing care needed by newborn infants during the day, evening, and night periods. Members of the auxiliary nursing staff should at all times work under the supervision of the supervisor or head nurse.

Ideally, the nursing staff for newborn infants in the suspect, or observation, nursery should be separate from that caring for well newborn infants. Since this is not practical in most hospitals, if technique is carefully observed these infants can be cared for by nurses of the regular nursery service. This plan has proved satisfactory when the observation nursery is adjacent to the regular nursery.

Members of the nursing staff of the isolation nursery must be separate from those caring for well newborn infants. This principle must be scrupulously adhered to in order to avoid cross-infection between the isolation and clean nurseries.

PERSONNEL HEALTH POLICIES

The hospital should establish a plan for the health services of its personnel, including those pediatric, nursing, housekeeping and cleaning personnel working in the newborn service. Such a plan should include a preemployment and periodic, usually annual, physical examination including a chest x-ray, and a plan *for the immedi-*

From the Department of Pediatrics, New York Medical College, Flower and Fifth Avenue Hospitals.

(*b*) Standards and Recommendations for Hospital Care of Newborn Infants: Full-Term and Premature, Publication 292, *Children's Bureau,* 1943.

[2] Losty, M.: Personal communication to the authors.

ate reporting of any illness suggestive of a communicable skin, gastrointestinal or respiratory disease. Such an illness would immediately exclude affected personnel from the newborn service, and they should not be permitted to return to their regular assignments until a physician has certified their recovery. The effectiveness of such a plan would depend on the early reporting of illness and early exclusion from duty. The use of routine stool, nose or throat bacteriological cultures has proved of doubtful value in the control of infection in a service.

PHYSICAL LAYOUT OF NURSERIES

The ideal physical layout consists of the following functional areas: (1) clean, or regular, nurseries for full-term newborn infants; (2) the suspect, or observation, nursery; (3) the isolation nursery, and (4) the formula-preparation room.

Clean, or Regular, Nurseries.—Functionally, the most practical location of the clean, or regular, nurseries is in close proximity to the respective postpartum rooms. This location will facilitate the easy transportation of all normal full-term newborn infants to their mothers for feeding.

Ideally, small nurseries should be provided. The most efficacious plan is to provide space for only eight full-term newborn infants in each nursery room. The chief advantage of such a provision is that, if infection should occur in a specific nursery, its spread, if any, would be limited to only a small number of infants.

A minimum average of 30 sq. ft. per bassinet should be provided in each nursery room to give adequate space around each bassinet, for the completely individualized care of each infant. This average square footage will provide nursery space for a sink and diaper, linen and disposal cans and will make it relatively easy to wheel the scale to the cribside for weighing. In addition, it will accommodate chairs in which the nurse can sit and hold those babies who for one reason or another cannot be taken to their mothers for feeding.

Equipment for each nursery room should be the simplest possible. There should be individual bassinets; a weighing scale on a movable table; a sink providing hot and cold running water and equipped with arm, foot or knee control; bar soap; disposable towels, and discard cans operated by a foot pedal for linen, diapers, and other soiled materials. Each bassinet should have a compartment for a 24-hr. supply of all equipment needed for each infant's care—diapers, linen, oil and its container, and a thermometer. The purpose of this principle of individual care is again to minimize the possibility of cross-infection. There should also be one modern, efficient incubator for every 16 infants, and oxygen and suction equipment for each nursery.

Each nursery room or set of two nursery rooms should have an anteroom and an examination and treatment room. The anteroom will be used primarily as a chart area and will also be the area where the physician scrubs and dons a mask and gown prior to entering the examination and treatment room. The examination and treatment room, as the name implies, is to be used for examination and treatment of infants and also for operative circumcision; it therefore should contain supplies and equipment for this purpose. In addition, it should contain a bottle warmer and refrigerator for formulas. As much glass panelling as possible should be provided between this accessory work space and the nursery proper for ease of observation and supervision.

The Suspect, or Observation, Nurseries.—When the regular nurseries for newborn are located on more than one floor, a suspect, or observation, nursery should also be provided on each floor to lessen the possibility of the introduction of infection from one floor to another. The suspect and clean nurseries should be as close to each other as possible, because they will possibly both be staffed by the same nurse. The data presented above on the regular nurseries, regarding capacity, size and equipment apply equally well to the suspect nursery. The suspect nursery should contain one bassinet for every eight bassinets in the clean, or regular, nurseries.

The suspect nursery is for observation of any newborn infant suspected of having an infectious condition. This nursery, therefore, should also care for newborn infants after a ritual circumcision because of their exposure to fairly large numbers of outside visitors and because of possible infection resulting from such exposure. The suspect nursery should be looked upon as a hub for diagnosis. Thus, any newborn infant suspected of having an infectious condition should be immediately removed to the suspect nursery. If, after a brief period of observation, a diagnosis of infection is made, he is to be removed to the isolation nursery; if on the other hand, an infant is found not to have an infectious condition, he may be returned to the regular nursery.

The Isolation Nursery.—When a general hospital has a well-organized pediatric service, it is more desirable to locate the isolation nursery on this service, since this service is better geared to the care of sick infants than the clean newborn service usually is. Furthermore, it is desirable that infection be removed from the clean service as quickly as possible. Once an infant has been removed to the isolation nursery because of the diagnosis of an infectious condition, he cannot be allowed to return to the regular, or clean nurseries. The data presented above on the regular nurseries regarding capacity, size, and equipment apply equally well to the isolation nursery. The isolation nursery should have one bassinet for each eight bassinets in the clean, regular nursery.

Formula-Preparation Room.—In this era when artificial feeding of newborn infants is not uncommon, formula preparation has become an important function of the newborn service. The formula room should be located away from any infected or contaminated area of the hospital and should be near, or easily accessible to, the largest number of infants it may serve.

In order to separate clean and unclean activities, it is desirable to provide a reception and clean-up room, and a formula-preparation room. In the former room, bottles, nipples, and nipple caps are received from the nurseries and thoroughly washed. In the latter room, formula mixtures are prepared and poured into formula bottles, which are nippled and nipple capped; terminal sterilization is performed at 230 F. for 10 min. or 212 F. for 25 min. Refrigeration may be provided centrally within the formula room or locally within the work-space area of the nurseries. Bacteriological testing of formulas and nipples should be performed by the hospital periodically, preferably weekly, to assure a safe product for the infants.

In general, the recommendations of the American Hospital Association manual on procedures and layout for the infant formula room [3] are valuable and serve as an excellent guide in formula preparation.

POLICIES AND PROCEDURES

The pediatric director, with the help of the supervising nurse of the newborn service, should establish policies and procedures for the functioning of this service. Such policies and procedures should be thoroughly discussed with all groups concerned prior to their establishment, so that those finally agreed upon will be feasible as well as scientifically desirable. For example, some of the procedures with which both the pediatric and nursing care are concerned and in which the availability of nursing time is a factor are (1) frequency of weighing of normal full-term infants; (2) daily care of the skin; (3) frequency of routine temperature taking; (4) use of routine house formulas; (5) use of abdominal binders and umbilical cord dressings; (6) use of gowns and masks by nursing personnel constantly working in clean nurseries.

In such procedures, emphasis must be placed on the elimination of nonessentials; thus, the time of the available nursing staff will be conserved for the really necessary jobs. The available time then may be used for essential procedures and for taking the normal full-term babies to their mothers for all daytime feedings. This latter practice eliminates the universally prevalent technique of propping bottles, with its potential danger of aspiration of formula; at the same time it gives the mother an opportunity to learn how to hold and feed her baby during the period of hospital stay and establishes the normal emotional child-mother relationship. Nursing time should also be available for teaching and educating the mother and father so that they will approach care of the infant with confidence and security.

In the establishment of such policies and procedures, it is usually desirable that a manual be prepared for joint use of the medical, nursing, and auxiliary staffs. This manual should contain emergency standing orders as well as a listing of the agreed-upon policies and procedures. One item of considerable importance is the establishment of policies for consultation with a qualified pediatrician, i. e., for sick and potentially sick newborn infants and for premature infants. In addition, similar policies should be established for consultation with the respective specialists for such conditions as congenital, orthopedic and cardiac deformities, and surgical conditions.

RECORDS

Complete and detailed records of the infant's hospital experience are as necessary for newborn infants as for all hospital patients. The newborn infant should have a record of his own that is separate from that of his mother. However, his record should include pertinent data regarding the mother's course during the antepartum, labor and delivery periods. Such data might include complications of pregnancy, labor and delivery; serological test and determination of the Rh factor; analgesia; anesthesia; length of labor and type of delivery. The record of the newborn infant should begin with his condition and care in the delivery room and should continue with his hospital neonatal course. It should include such items as weight, temperature, respiration, feeding and reactions to feeding, and stools. Admission and discharge physical examinations, progress notes, consultation notes and laboratory data, when indicated, are a necessity.

In addition to the clinical record of the individual newborn infant, it is desirable to have a worksheet or workbook in each nursery kept on a daily basis. Such a book or sheet should contain the name of each infant and such essential information as age; weight; temperature; condition of eyes, mouth, cord, skin, and buttocks; number, size, color and consistency of stools (a code may be used); urine; type and amount of feedings; treatment; medications, and remarks.

COORDINATION OF CARE IN THE HOSPITAL AND IN THE HOME

Ideally, a hospital should have a plan by which, at the request of a physician, all newborn infants are visited in the home by members of a community nursing agency immediately after discharge from the hospital. The purpose of such home visiting is to help the parents carry out the instructions on care of the baby in the home; in other words, such visiting is a link between the teaching program within the hospital and that given through health supervision during the infant's early months and years of life.

However, in this era of nursing shortages, it may not be possible to have all newborn infants visited in the home. Therefore, priority for visiting must be established. Such priority may be given the following infants: those prematurely born; the newborn with birth injuries or congenital malformations, and those born of primiparous or insecure mothers. Each of the above categories may have special problems with which the parent or parents may need considerable assistance.

ACCESSORY SERVICES NECESSARY

Laboratory and x-ray services with an adequate technical staff should be provided within the hospital, so that they will be available when needed for the newborn. There should be a qualified hematologist or pathologist and radiologist, respectively, in charge of such services. Furthermore, post-mortem facilities should be provided, if there is to be an opportunity of learning the lessons potentially available from a review of individual neonatal deaths.

Social service is most important. A social worker can be of great assistance in such problems as placement of illegitimate infants and of babies with such deformities as mongolism, hydrocephalus, and meningocele. She can assist in making a plan for further care of infants with birth injury, congenital cardiac, orthopedic and ophthalmological deformities.

CONCEPT OF FUNCTION OF THE NEWBORN SERVICE

In a general hospital the maternity and newborn services are the only two largely composed of well or normal people. Despite this unique difference, these normal, well, maternity patients and newborn infants have been treated and managed as sick individuals. To our way of thinking, this treatment is entirely artificial and unnecessary and one which works to the disadvantage of the patient. For example, it seems useless to take the temperature of a normal full-term newborn infant routinely every four hours. It likewise seems impractical to look upon such an infant as a "sterile product" that must remain such and therefore cannot be taken out to its mother until the time of discharge of mother and baby from the hospital.

---

[3] Procedures and Layout for Infant Formula Room, Chicago, American Hospital Association, 1949.

More and more within the past few years the obstetrician, pediatrician and general practitioner have come to recognize the fallacies in such practices. Certainly, rooming-in when carefully planned has several advantages for the parents and their newborn infant. Not only can the postpartum hospital stay be used as a period of instruction of the parents, but, even more important, the rooming-in plan is an excellent device to foster desirable parent-child relationships and the development of a healthy personality in the child.

SUMMARY

A plan for hospital service for newborn infants is discussed. Topics of this discussion are pediatric care, an adequate nursing staff, personnel health policies, the physical layout and equipment of nurseries, policies and procedures, records, coordination of care in the hospital and in the home, and accessory services. The value of a more flexible system in the hospital care of newborn infants is pointed out.

MIDFORCEPS OPERATIONS

INDICATIONS FOR AND RESULTS OF ONE THOUSAND CASES BASED ON PELVIRADIOGRAPHY AND PROGRESS OF LABOR

Arthur Weinberg, M.D., Far Rockaway, N. Y.

In modern obstetrics, the midforceps operation has become the chief delivery room problem. This operation is usually selected for completion of deliveries in cases of midpelvic arrest caused by malposition or poor uterine or abdominal contractions.

The definition of a type of forceps operation must include reference to fetal and pelvic planes that are ascertainable and constant. For the fetal point of reference, the use of the biparietal diameter is not wise, because in the average obstetrical forceps operation, the obstetrician contents himself with the station of the most dependent portion of the presenting part and the location of the sutures and fontanels for determining position and station. The location of the biparietal diameter is easily determined by a lateral roentgenogram, but determination of its level in the pelvic axis by manual examination is difficult. I, therefore, use and urge the adaptation of the most dependent portion of the presenting part, excluding a caput succedaneum.

Likewise, the pelvic points of reference must be fixed and locatable either by roentgenogram or manually. The use of the ischial spines for designation of the midpelvis and the perineum for the outlet is illogical, because the perineum may be absent in third degree tears or depressed in lacerated perineums in relation to the true pelvis, and furthermore the muscles are not discernible by roentgenograms. The logical plane for one to select as the station of the outlet is the level of the ischial tuberosities, which are fixed and easily located roentgenographically or manually. The plane of the inlet is, of course, the linea terminalis at the level of or slightly below the true conjugate. Therefore, the following definitions are suggested.

A midforceps operation is an obstetrical operation by which a fetus which presents cephalically and whose presenting part is located in the midpelvis, that is, between the planes of the ischial spines and ischial tuberosities, is delivered by forceps. In a floating forceps delivery, the most dependent part lies above the inlet. In a high forceps operation, the presenting part lies between the inlet and spines, and in a low forceps, it lies below the tuberosities. An outlet forceps operation is delivery of a fetus by forceps whose presenting part is easily visible and is distending the perineum and vulva.

Midforceps deliveries are sometimes performed when the patient has been fully dilated for two hours without progress, and the cause of the delay is not known. In some cases, a midforceps operation is indicated when undue maternal distress is apparent either from hemorrhage, toxemia, cardiac disease, tuberculosis, infection, or exhaustion from prolonged labor.

In cases of sudden development of fetal distress from a prolapsed cord, intrapartum hemorrhage, or intrauterine asphyxia from the labor itself, if proper conditions exist, a midforceps operation is selected as the best chance for delivery of a baby before it succumbs to the unfavorable influences of its environment.

In some cases of midpelvic arrest caused by cephalopelvic disproportion, the forceps are wrongly used to terminate labor, and the maternal morbidity and fetal mortality are usually prominent in this type of case. Whereas forceps are contraindicated in cases of disproportion, they are sometimes of great value in delivery of the arrested vertex in cases of pelvic contraction. If the planes and segments of contraction and the pelvic architecture are determined by pelviradiography, the forceps may be used to direct the vertex into relatively more ample planes and segments of the pelvis. By control of the position of the vertex, the various cephalic

diameters may be presented to the diameters of the pelvis in such a manner that delivery is facilitated. It is by such considerations that Mengert[1] and Caldwell, Moloy, and D'Esopo[2] have attempted to make the forceps operation more of an art than a simple trial and error method of the application of force to a problem arising from the mechanism of labor.

In recent years the indications for forceps operations have been extended to include the solution of soft part dystocia in many of its aspects. In the first stage of labor the cervix may be dilated to 8 cm. and then, notwithstanding the proper combination of time, rest, sedation, intravenous glucose solution, and oxytoxic stimulation, dilatation may cease. Maternal or fetal distress at this stage may indicate the advisability of the termination of labor. If all the other conditions for a forceps operation are present except the fully dilated cervix, namely, engaged head, no disproportion, membranes ruptured, and position known, one may occasionally be able to apply forceps and deliver successfully if the cervix is negotiable or can be made so by regional pudendal, caudal, or saddle block anesthesia, or by general anesthesia. There are also some cases of constriction ring dystocia that can be handled in a similar manner.

Dystocia at the inlet is more readily recognized both clinically and by roentgenogram and early enough for abdominal delivery to be selected rather than a high forceps operation. Outlet dystocia alone must be very rare, because the outlet is almost always more ample than the midpelvis. The only exception is if the pelvis is deformed by injury or metabolic or deficiency diseases, in which case significant outlet dystocia without midpelvic dystocia is possible.

In my own experience, therefore, the chief problem in the delivery room is midpelvic arrest. I and many of my colleagues and associates give more consideration to the decision of performing a midforceps operation than we do to any other obstetrical problem. We look for indications and contraindications to justify our decision. If the result is poor, a question arises: Did we interfere too soon or too late? I know of no other obstetrical decision about which there is always so much criticism and difference of opinion. I have seen many well-trained obstetricians hesitate and procrastinate before attempting an inevitable midforceps operation. On the other hand, we have undoubtedly at times interfered too soon with tragic results. In an attempt to more clearly define the indications and contraindications for the operation, a study of 1,000 patients delivered by midforceps was made. To eliminate unknown factors relating to pelvic architecture and size, only patients who had been subject to pelviradiography were included.

INCIDENCE

The incidence of midforceps operations as represented in this series is difficult to determine, because the material analysed is drawn from many different sources. All were patients on whom midforceps operations were performed, who had had pelviradiography done, and at whose delivery I was present either as the attending or consulting obstetrician or the radiologist. The patients were delivered at the following institutions: Queens General, St. Joseph, Rockaway Beach, Beth Israel, South Nassau Communities, and Mercy Hospitals, all in New York State. In my own practice, the incidence was 11%.

Of the midforceps operations, 72.8% were done on primiparas and 27.2% on multiparas. Since the distribution of primiparas and multiparas in this area is about equal it is clear that the operation is definitely more frequent in primiparas. However, since 27.2% of the midforceps operations were performed on multiparas, it follows that when a multipara is in labor the entire problem is not just for one to await a call that the patient is ready, and then to arrive in time to deliver the baby.

DURATION OF LABOR

The duration of labor at times is difficult to estimate because the onset is often indefinite. A prolonged labor is by definition a labor of 30 hours. From the viewpoint of the patient and her family, labor usually causes anxiety from the time of admission to the hospital. In this series, labor was considered as beginning when contractions were regular, were under 10 minutes, and affected the cervix either by effacement or dilatation. The irregular contractions of uterine hyperirritability were not considered as part of labor.

TABLE 1.—*Incidence of Normal and Prolonged Labor*

Stage of Labor	Normal, %	Prolonged, %
First stage	81.8	18.2
Second stage	91.4	8.6
Both stages	....	2.4

The first and second stages of labor are somewhat different from each other both in the muscles utilized and in the physiological result. The difference is emphasized by study of the incidence of prolonged labor of each stage. I consider a prolonged first stage one over 24 hours. Table 1 indicates that even though a prolonged first or second stage occurred in 26.8% of the cases, in only 2.4% were they combined. This further emphasizes the essential difference between the two stages. In a series of midforceps deliveries, a fairly high incidence of prolonged labor is expected. The usual incidence of prolonged labor is about 3% of all cases. In a series of 85 prolonged labors, Bradford and Woltz[3] reported an incidence of midforceps of 49% and 11% of other major operative procedures. The midforceps operation has always been a mainstay in the termination of prolonged labor, but it should be realized that after 50 hours of labor, 60% of the cases never reach full dilatation, and the conclusion is inescapable that more labor will seldom result in further dilatation or easier delivery. After prolonged labor, the fetal mortality and maternal morbidity of midforceps operations rise sharply, and the attempt to shorten labor before the 50 hour deadline by safe means should be considered.

INDICATIONS

The indications for forceps operations have been divided according to custom into maternal and fetal indications (table 2). If more than one indication was present, for the sake of simplicity only the major indication was considered. However, in 5.6% of the patients, no obstetrical indication was involved. These operations were usually performed because the station of the vertex was misjudged to be lower than it actually was. Others were delivered because they were under anesthesia when the diagnosis was made. These were usually in multiparas who were anesthetized prematurely by the nursing staff to prevent precipitate delivery. There were some patients delivered without any other indication except that an uncooperative patient was raising such havoc or making such a loud noise that for everyone's comfort the delivery was anticipated by a midforceps operation if the conditions were favorable and no contraindications were present.

TABLE 2.—*Maternal and Fetal Indications for Forceps Operations*

Indication	Percentage
No indication	5.6
Maternal	
Arrest	91.8
Poor contractions	21.8
Lack of voluntary effort	11.8
Combination of poor contractions and lack of voluntary effort	6.0
Pelvic soft part dystocia	8.0
Contracted pelvis	2.0
Disproportion	0.4
Impacted shoulder	0.4
Imprisoned anterior lip	0.2
Cervical rigidity	0.2
Extended head	0.2
Arrest occiput posterior	5.2
Persistent malposition	24.6
Malposition	11.0
Distress	0.6
Exhaustion	0
Hemorrhage	0
Tuberculosis	0
Cardiac	0.2
Toxemia	0.4
Fetal	
Distress	2.0
Asphyxia	1.6
Hemorrhage	0.2
Prolapse of the cord	0.2

There are two groups of maternal indications: arrest or distress during labor. By arrest is meant a lack of progress in either descent or rotation. Definite progress is expected within two hours of good second stage labor contractions if the membranes are ruptured. Very slight progress is of no avail, and unless the labor is progressing toward an easy delivery, further procrastination is usually of no avail, and if no disproportion exists, the results of a midforceps delivery at this time are as good if not better than those attempted after a much longer second stage during which the baby may be damaged by cerebral concussion, intracranial hemorrhage, or be asphyxiated by a tight cord or one shortened by coils around the fetal neck. Such events cannot always be detected by auscultation of the fetal heart, and obstetricians are sometimes surprised to see an asphyxiated baby emerge when the fetal heart was regular and of a normal rate.

If the second stage contractions are weak, progress may well be unexpected within the prescribed time limit. Instead of waiting longer, after one hour I prefer to stimulate the second stage contractions by rupturing the membranes if they are still intact. This usually results in an acceleration of progress in labor. If after one-half hour the contractions are still not powerful, I use oxytocin injection (pitocin®) hypodermically in doses of 1 or 2 minims (0.06 or 0.12 cc.) every 20 minutes for one hour or an intravenous infusion of dilute oxytocin injection. If the contractions fail to result in descent and in rotation, the time indication for midforceps delivery is invoked. I usually look for progress in descent rather than in rotation, because in observing malposition by pelviradiography, I found that if rotation fails to occur during the first stage of labor when the vertex is meeting cervical resistance, or when the membranes rupture allowing flexion, then the next chance is when the presenting part reaches the inclined pelvic floor and the vertex is then in low pelvis, and the midpelvic plane and forceps are bypassed. Therefore, one need not expect spontaneous rotation in the midpelvis once the membranes have ruptured; it certainly is rare. If the vertex is in the occiput posterior or transverse position and if it will not descend below the midpelvis to the perineum, artificial rotation must be substituted in the great majority of cases. This failure of rotation is the indication for 40.8% of the midforceps operations. In seven out of every eight cases in which spontaneous rotation failed to occur, operative rotation was effected, whereas one out of every eight patients had to be delivered by traction to the direct occiput posterior position.

CHOICE OF FORCEPS

While the skill and experience of the operator are more important than the selection of the variety of forceps to be used, I *do not subscribe* to the view of some that a good forceps technician should be able to perform all varieties of forceps extraction equally well with the one instrument with which he is most familiar. The varieties of pelvic architecture and of pelvic contraction dictate that maneuvers should be so selected as to make use of the most favorable diameters.[4] If malposition exists, the decision to rotate at the level of arrest or above or below it is of great import.[5] In this study, six types of forceps were used.

[5] Weinberg, A.: West J. Surg. 48: 227, 1940.

PELVIC SIZE

There were no patients with contracted pelvic inlet who were delivered by midforceps. If a patient has a contracted inlet with a borderline or relative disproportion, and a trial of labor does not result in descent below the midpelvis, the patient is not delivered by midforceps but by abdominal section. In the recent study of midforceps deliveries by Steer,[6] about 70% were done for disproportion with a corrected fetal mortality of 3.8%.

There were 2.8% of contracted midpelvis in this series: those in which the interspinous was 9.5 cm. or less, or the posterior sagittal 4.0 cm. or less, none of which were associated with a contracted inlet. The association of a contracted inlet and midpelvis was considered to be an indication for abdominal delivery for a full term pregnancy.[7] In no case was a midforceps delivery of a full term pregnancy attempted when the midpelvic index (sum of the interspinous and posterior sagittal) was less than 13.5 cm.[8] There were six cases of contracted outlet (sum of bituberous diameter and posterior sagittal less than 16.5 cm.). The pelvic outlet index always equals or exceeds the midpelvic index so that it cannot be the definitive cause of disproportion unless there is a funnel effect caused by converging side walls, a narrow subpubic angle, and lower sacral variations. All cases of contracted pelvic outlet were associated with contracted midpelvis. When present, contraction of pelvic outlet and midpelvis contributed to arrest in low pelvis in those cases in which the vertex had passed the plane of least pelvic dimensions, that is, the midpelvis.

RESULTS

The results of any obstetrical procedure ultimately will decide its place in practice.

Mother.—Fortunately there was no maternal mortality. A total of 7.8% significant complications occurred, distributed as follows: sulcus tear 3.2; postpartum hemorrhage 1.6; urinary retention over two days 0.6; third degree perineal laceration 0.6; cervical laceration 0.6; postpartum infection 0.2; parametritis 0.2; Dührssen's cervical incisions 0.2; manual removal of placenta 0.2; phlebitis 0.1; inversion of uterus 0.1; paravaginal hematoma 0.1; fistula in ano 0.1.

Baby.—The fetal mortality was 0.6%. The six deaths were distributed during labor and after delivery as follows: intra partum death (during labor but before delivery), one; stillborn (death during delivery), two; neonatal deaths, three.

Intra partum death was caused by cord strangulation during descent due to three loops of cord around the neck.

Of the stillborn, the first was a 12 lb. baby (5,443.1 gm.) in which death was due to traumatic asphyxiation from impacted shoulders in a multipara. This fetal death was caused by disproportion due to an excessive sized baby in a very obese woman with a family history of diabetes, who is probably also a candidate for this disease. The second was in a primagravida with a 10 lb. (4,535.9 gm.) stillborn baby with a clinical birth injury caused by failure of forceps delivery and subsequently delivered by internal podalic version and breech extraction. An unrecognized malposition was the cause of the failure of forceps operation. Incidentally both of these patients had uncomplicated forceps deliveries with live babies at their next confinements; this rules out contracted pelvis as the cause of the stillbirths.

The three neonatal deaths were due to the following causes: (1) unrecognized occiput posterior with clinical birth injury, no autopsy being performed; (2) an intracranial hemorrhage proved by autopsy that occurred in an uncomplicated midforceps delivery; (3) unknown. Clinically there appeared to be no birth injury.

There were six nonfatal birth injuries all followed by complete recovery: cephalhematoma, two, or 0.2%; transient Erb's palsy, two, or 0.2%, and transient facial palsy, two, or 0.2%. As is well known, intracranial hemorrhage, Erb's palsy, and cephalhematoma may occur in spontaneous deliveries as well and in nearly the same proportion.

COMMENT

In this series of 1,000 midforceps deliveries in patients whose pelves were studied by pelviradiography either before or during labor, the maternal and fetal results were almost as good as could be expected in spontaneous deliveries, and much better than in any series of cesarean sections performed after labor began with which I am familiar.

The tendency in the current literature is to urge almost complete elimination of the midforceps operation: Steer's [6] results in his study of 227 midforceps operations were so poor that he recommended that it be seldom performed. The incidence of complications in his series was as follows: hemorrhage 15%, cervical lacerations 12%, Dührssen's incisions 3%, sulcus tear 23%, fistula 0.4%, maternal mortality 0.4%, and uncorrected fetal mortality 7% corrected to 5.3%.

The indications for the midforceps operation in Steer's series were divided into disproportion 70% and inertia 30%, whereas in my series the corresponding figures were 0.4% and 28%. By contrast, the fetal mortality in the disproportion group was 5.3% in his series, and 0.5% in mine. I never perform a midforceps operation in the presence of known disproportion. The deaths in this series were due to nonrecognition of excessive size babies in pelves of average size.

D'Esopo [9] states that only by reduction of the midforceps incidence to 0.5% and increase of the cesarean rate to 6% will it be possible to eliminate birth trauma to mother and babies and maintain a preventable term fetal loss of 1%. I have kept my preventable term fetal loss to 0.5% with a cesarean incidence of 3% and a midforceps rate of 11%. When one considers that the incidence of rupture of the uterus in subsequent pregnancies occurs in 1.7% and a very thin scar is found in another 2.3%, the later advantages of vaginal delivery are obvious. The immediate complications in 1,000 consecutive cases of cesarean section at Sloan Hospital for Women during the same period as my midforceps series were much higher: infection 10.7%, hemorrhage

14.6%, wound infection 33%, wound disruption 0.2%, thromboembolism 1.8%, intestinal obstruction 0.2%, distention 23.6%, and respiratory 2.8%.

The major indication in my series for midforceps is malposition (40.8%). Rotation of a malposition in the absence of disproportion was performed 356 times without fetal mortality or serious injury. Fifty-two patients with malposition were delivered by midforceps without rotation. According to D'Esopo and Steer, these patients should have been subjected to further labor or section. At least 246 had the further trial of labor up to a full test. Prolonged second stage labor in itself is dangerous, and further trial might have compromised the baby and run the risk of uterine rupture. The other patients were delivered for miscellaneous indications; none required cesarean section as judged by the fetal and maternal results.

The relatively good results in this series are due, I believe, to the use of pelviradiography. Every patient had the benefit of this procedure either before or during labor. The roentgenographic pelvimetry ruled out pronounced pelvic contraction and almost eliminated cephalopelvic disproportion. The knowledge that, if a proper cephalic application is made, sufficient traction will result in delivery gives the operator a feeling of confidence. In only one case did the forceps fail to deliver, and that was because a cephalic application was not made owing to nonrecognition of the position. The knowledge of pelvic architecture aids in the proper selection and execution of the forceps operation. The roentgenogram, incidentally, in a number of cases was a check on a manual determination of station and position.

In cases of borderline midpelvic contraction with possible cephalopelvic disproportion at this plane, a full test of labor is given to allow the biparietal diameter to pass the ischial spines. This was determined by the presenting part being at or slightly below (1 cm.) the ischial tuberosities. If the vertex in an anterior position failed to reach this level, I suspected that the biparietal diameter could not pass through the plane of least dimensions, and a midforceps delivery was not attempted.

SUMMARY AND CONCLUSIONS

The midpelvis is defined as that portion of the true pelvis lying between the ischial spines and tuberosities. In a series of 1,000 midforceps operations in women who had the benefit of roentgenographic pelvimetry before or during labor, the uncorrected fetal mortality was 0.6%, corrected to 0.5%. There was no maternal mortality. The indication for the operation was arrest in 91.8%, of which 40.8% were due to malposition and 39.6% to poor contractions. Only 0.4% were due to disproportion. Distress accounted for 2.6%. The good results in midforceps operations performed in the absence of fetopelvic disproportion are indications for its retention rather than its almost complete replacement by cesarean section.

PREVENTION OF RHEUMATIC FEVER BY PROMPT PENICILLIN THERAPY OF HEMOLYTIC STREPTOCOCCIC RESPIRATORY INFECTIONS

PROGRESS REPORT

Benedict F. Massell, M.D., George P. Sturgis, M.D., Joseph D. Knobloch, M.D., Richard B. Streeper, M.D., Thomas N. Hall, M.D.

and

Pliny Norcross, M.D., Boston

The role of the hemolytic Streptococcus in the precipitation of both initial and recurrent attacks of rheumatic fever is now well established. Furthermore, it is general experience that hemolytic streptococcic respiratory infections in children and young adults who have previously had one or more attacks of rheumatic fever cause recurrence of the disease in 40 to 50% of instances. When the usefulness of sulfonamides in the treatment of streptococcic infections was first discovered, attempts were made at the House of the Good Samaritan to prevent such recurrences by prompt treatment of hemolytic streptococcic infections in known rheumatic subjects with a sulfonamide preparation in the hope that, by suppression of the growth of streptococci in the upper respiratory tract, absorption into the blood stream of the streptococcic substance responsible for precipitating the rheumatic process would be reduced to a subeffective level. These attempts were not successful.[1] Subsequently, when penicillin became available, it seemed reasonable to believe that this antibiotic might be effective where sulfonamides had failed, the basis for this belief being that in vitro penicillin was found to be a more potent antistreptococcic agent than the sulfonamides and that in vivo penicillin was observed to be more effective than the sulfonamides in eradicating hemolytic streptococci from the throats of carriers and of persons with acute hemolytic streptococcic respiratory infections.[2]

From the House of the Good Samaritan (Children's Medical Center) Boston.

Read before a meeting of the American Heart Association, San Francisco, June 22, 1950.

This study was supported by a research grant from the Helen Hay Whitney Foundation.

Most of the oral penicillin used in this study was supplied by the Lederle Laboratories through Dr. Stanton M. Hardy.

Consequently, in 1945 we began the studies that form the basis of the present report. Our preliminary observations were presented before the American Medical Association in June, 1948, as part of a broad study on various applications of penicillin to the rheumatic fever problem.[2b] Since that time, observations have been continued, and now we have accumulated data on a total of 46 proved clinical hemolytic streptococcic infections in subjects with proved rheumatic fever. Although not even this number of infections is sufficient to permit final conclusions, especially when consideration is given to the number of different serological species of streptococci involved in the infections, the possible practical application of our observations in relation to the problem of rheumatic fever prevention and the interest in such an application expressed at the recent National Conference on Cardiovascular Diseases[3] indicate the need of this progress report.

METHODS OF STUDY

The present report is based on observation on 46 clinical hemolytic streptococcic infections in 40 rheumatic subjects. Thirty-four persons had one infection each; whereas six persons had two infections at different times during the period of the study. With the exception of a 21-year-old girl the patients varied in age from 4 to 16 yr. The average age was slightly less than 10. Fifteen of the infections were in males; 31 were in females.

All the patients were proved rheumatic subjects, in that all gave a good history of one or more attacks of rheumatic fever. Furthermore, most of them had been observed by us personally at the time of at least one of the attacks, and 39 of the streptococcic infections occurred in persons with definite signs of rheumatic heart disease. Seventeen of the infections occurred in patients on the wards of the House of the Good Samaritan, seven in patients convalescing in one of the nursing homes of the Children's Mission to Children, and 22 occurred in ambulatory persons who were being observed carefully in connection with a so-called home study. The patients in the last group were examined in a clinic at weekly intervals and, in addition, were visited in their own homes at the time of all illnesses.

Base-line clinical and laboratory data had been collected on nearly all the patients for some time prior to the development of the streptococcic infections. The preinfection observations included throat cultures for hemolytic streptococci one to three times weekly and determination of the erythrocyte sedimentation rate and the antistreptolysin O titer of the serum at two to four week intervals. At the time of all febrile illnesses, whether or not these were associated with respiratory symptoms, the tests were repeated, and during the subsequent two months the frequency of the tests was increased. Throat culture swabs were planted and streaked directly on blood agar plates containing 5% horse blood. The antistreptolysin O titer was performed by a modification of the method of Hodge and Swift.[4]

In this study we have included only those infections with which there was fever as well as bacteriological evidence of invasion of the upper respiratory tract by hemolytic streptococci. In addition to fever, other symptoms and/or signs of pharyngitis or tonsillitis were usually, but not invariably, present. Pharyngeal or tonsillar exudate was not always observed.

The bacteriological evidence of streptococcic infection in most instances consisted in a change of the throat culture from negative to strongly positive for the hemolytic Streptococcus. In three patients there was a change in the throat culture findings from occasionally weakly positive prior to the clinical infection to strongly positive at the time of the infection. In several patients numerous hemolytic streptococci were cultured from the throat at the time of the clinical signs of infection, but preinfection cultures had not been taken. Subclinical hemolytic streptococcic respiratory infections, in which bacteriological evidence of infection was not accompanied by fever or other clinical manifestations of respiratory illness, were occasionally encountered, but, because of the difficulty in evaluation of these, they have not been included in the present study.[5]

Of the total of 46 clinical hemolytic streptococcic infections, 34 were treated with penicillin. For various reasons 12 infections were not treated with penicillin; these, therefore, served as controls.

In the treated group of patients, an attempt was made to begin therapy as soon as possible after the onset of clinical manifestations of infection; thus the administration of penicillin was usually begun immediately after the throat cultures had been taken and before the results of the cultures were known. Consequently, penicillin therapy was started in many suspected streptococcic infections in which the bacteriological findings failed to substantiate the diagnosis. In these instances, penicillin treatment was discontinued when the results of the throat cultures were obtained, and such infections were excluded from the study. In all streptococcic infections in which the diagnosis was confirmed by the bacteriological findings, penicillin treatment was continued for a total of 10 days. The time that elapsed between onset of symptoms and the beginning of penicillin therapy was usually less than 24 hr., occasionally 36 hr. and in one instance as long as 48 hr.

Five of the patients were treated intramuscularly with aqueous penicillin G in divided doses totaling 120,000 to 400,000 units per day. In the remaining patients, penicillin was administered by mouth in the form of buffered tablets of sodium or procaine penicillin G and usually in doses of 200,000 units five times daily (total of 1,000,000 units per day). For some patients treated at home it was found more practicable to change the dosage schedule after the first five days of treatment to 300,000 units three times daily. Care was always taken to prevent the mixing of penicillin with food by administration of the antibiotic at least one hour before meals and two to four hours after meals. Patients receiving penicillin were not allowed food between meals.

[4] Hodge, B. E., and Swift, H. F.: Varying Hemolytic and Constant Combining Capacity of Streptolysins: Influence on Testing for Antistreptolysins, J. Exper. Med. 58:277-287 (Sept.) 1933.

[5] Our preliminary report[2b] included five instances of penicillin-treated subclinical hemolytic streptococcic infections none of which was followed by rheumatic fever. Since the preparation of that report we have made no attempt to study subclinical infections; nevertheless, we are aware of two rheumatic fever recurrences which followed untreated infections of this kind.

An attempt was made to determine by the precipitin technique [6] the serological group and type of all strains of streptococci isolated at the time of the infections. Occasionally the strains were temporarily stored in the frozen state, and unfortunately in some of these instances the organisms did not remain viable and consequently could not be tested for their serological characteristics. Data regarding the frequency of group A strains among the hemolytic streptococci isolated from the 46 infections are presented in Table 1. Here it is shown that among the 34 penicillin-treated infections the causative organism was found to belong to group A in 25 instances. In four cases the isolated strains did not belong to group A, and in five instances the streptococci did not grow out and therefore could not be tested. Of the 12 infections not treated with penicillin, 11 were found to be due to group A streptococci.

Table 1.—*Data Regarding Frequency of Group A Strains Isolated from 46 Hemolytic Streptococcic Infections*

	Infections Not Treated with Penicillin	Infections Treated with Penicillin	Total Infections
Strains not isolated for grouping	1	5	6
Non-Group A strains............	0	4	4
Group A strains.................	11	25	36
Total........................	12	34	46

Information regarding the serological type of the group A strains is given in Table 2. Of the 25 group A strains isolated from the penicillin-treated infections, 10 could not be typed with the available precipitin serums. These are referred to as type X. Of the 11 group A strains isolated from the infections not treated with penicillin, three were found to be type X.

FREQUENCY OF RHEUMATIC FEVER RECURRENCES

The frequency with which rheumatic fever recurrences followed the penicillin-treated and the untreated hemolytic streptococcic infections is indicated in Tables 3 and 4. In Table 3 the data have been analyzed without regard to the serological characteristics of the organism isolated at the time of the streptococcic infections, whereas in Table 4 the analysis has been restricted to infections demonstrated to be due to group A streptococci. It is evident that rheumatic fever recurrences followed approximately one-half of the untreated infections, an incidence which is consistent with our previous experience at the House of the Good Samaritan. In contrast, only two (6% to 8%) of the treated infections were followed by rheumatic fever.

Table 2.—*Serological Types of Group A Strains Isolated from 36 Streptococcic Infections*

Type	X*	2	3	4	5	6	12	22	30	41	Total Group A Strains
No. of infections not treated with penicillin	3	0	2	0	2	3	0	0	0	1	11
No. of infections treated with penicillin	10	3	1	1	6	1	1	1	1	0	25
Total infections..................	13	3	3	1	8	4	1	1	1	1	36

* Type X is used to designate those strains which could not be typed with the available serums.

In evaluation of these findings, attention should be called to the fact that in the penicillin-treated series of group A infections the isolated strains could not be typed with the available precipitin serums in 10 instances, and in two instances the streptococci were found to be either type 4 or type 22, two serological types that are believed by many investigators to be frequently nonrheumatogenic. In the untreated infections, type 4 and type 22 strains were not encountered; however, the organisms isolated from three of the infections could not be typed with the available serums. Both of the rheumatic fever recurrences in the penicillin-treated patients resulted from type 2 streptococcic infections. In the control series, recurrences followed streptococcic infections due to type 3 in one case, type 5 in two cases, type 6 in one case, and type X in two cases. None of the untreated infections was due to a type 2 Streptococcus.

Because of these variations in the serological characteristic of the organisms responsible for the respiratory infections and because of the total numbers of infections in the treated and especially in the control series, which are too small for a test of statistical significance, the results of this study should be interpreted with some reservations, and final conclusions should not be made until there has been an opportunity to observe a larger series of infections represented by a wider variety of serological types of streptococci.

Table 3.—*Frequency of Rheumatic Fever Recurrences Following Streptococcic Infections—Irrespective of Serological Group of Isolated Strains*

	No. of Infections	Recurrences

	No. of Infections	Recurrences	
		No.	%
Infections not treated with penicillin.	11	6	54
Infections treated with penicillin.....	25	2	8

Nevertheless, the difference in incidence of recurrences in the treated and untreated groups of patients is impressive and suggests that penicillin therapy of hemolytic streptococcic infections may be effective in preventing subsequent rheumatic fever. This impression is strengthened by the fact, previously mentioned, that prior to the use of penicillin at the House of the Good Samaritan hemolytic streptococcic infections were usually followed by rheumatic fever recurrences in 40% to 50% of instances. The clinical chart of one such rheumatic recurrence (Fig. 1) and, for comparison, the clinical chart of a patient successfully treated with penicillin at the time of a hemolytic streptococcic infection (Fig. 2) are shown.

A more detailed consideration of the clinical course and bacteriological findings in the two patients in whom rheumatic fever developed despite penicillin therapy supports the belief that penicillin played a role in the prevention of rheumatic fever in the remaining patients who were treated with this antibiotic. Both patients in whom therapy failed were convalescing in the same nursing home, and both experienced type 2 streptococcic respiratory infections within a short time of each other—one first became ill on Feb. 2 and the other on Feb 16, 1950. A type 2 clinical streptococcic infection also developed shortly afterward in a third patient who was treated with penicillin and in whom a rheumatic recurrence did not develop. Furthermore, during this same period, type 2 organisms were cultured from the throats of several other patients and personnel in the nursing home who did not present any clinical evidence of respiratory disease.[7]

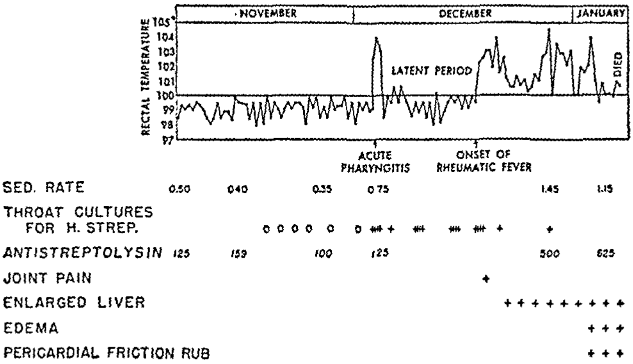

Fig. 1.—Clinical chart of a patient in whom a fulminating and fatal recurrence of rheumatic fever followed a hemolytic streptococcic infection. This episode was observed at the House of the Good Samaritan prior to the discovery of penicillin. Note presence of positive throat cultures and rise in antistreptolysin 0 titer.

Through a misunderstanding, the first patient in whom the type 2 infection developed was not treated with the usual oral dose of penicillin (200,000 units five times daily) until three days after the onset of his first symptoms. Instead, he received two doses of 200,000 units each on the evening of the first day (12 hours after the onset of clinical manifestations) and only 100,000 units five times during the second day. Despite this delay in the use of full penicillin dosage, the clinical respiratory manifestations subsided promptly and the throat cultures became negative for hemolytic streptococci. On Feb. 15, three days after discontinuation of penicillin therapy and 13 days after the onset of the initial streptococcic infection, the patient again experienced a high fever and the throat culture once more revealed the presence of numerous type 2 streptococci. This recurrent infection was treated within 12 hours with full oral doses of penicillin (200,000 units five times daily) and during a 10-day course of therapy the patient became clinically well and apparently free from streptococci. A throat culture taken five days after discontinuation of the second course of penicillin was reported as negative, but after another seven days (22 days after the second streptococcic infection) fever, joint pains, and other manifestations characteristic of rheumatic fever suddenly developed. A throat culture taken at this time revealed once more the presence of numerous type 2 streptococci. A clinical type 2 streptococcic infection developed in the second patient on the evening of Feb. 16, the day after the recurrence of infection in the previously described patient. This second patient received 200,000 units of penicillin orally within several hours after his first clinical symptoms and then, beginning the next morning, 1,000,000 units daily for another 10 days. Although there were no further clinical signs of respiratory infection, type 2 organisms reappeared in large numbers in the throat culture beginning one week after administration of the last dose of penicillin and were frequently cultured from the throat thereafter. About four weeks after the initial streptococcic infection and 10 days after the first reappearance of type 2 streptococci in the throat, the patient became ill with definite manifestations of rheumatic fever.

From the available facts it is not possible to determine whether the return of type 2 streptococci in the throats of these two patients after the discontinuation of penicillin therapy was due to reinfection contracted from other persons in the same house who harbored the organisms and to whom they were exposed or whether it was due to suppression but incomplete eradication of the streptococci from the respiratory tract during therapy and subsequent regrowth of the organisms, when they were no longer subject to the influence of the antibiotic. In either case it is evident that recurrent streptococcic infections developed in both patients, and it seems possible that these infections were responsible for the rheumatic fever which developed shortly thereafter.

Support for this interpretation is offered by the follow-up throat culture data obtained in 30 of the 32 remaining penicillin-treated patients, in none of whom did rheumatic fever develop. In 25 of these, the throat cultures became negative for hemolytic streptococci soon after the beginning of penicillin therapy and remained negative after the discontinuation of the antibiotic. In four cases, the throat cultures remained negative during therapy but occasional weakly positive cultures, indicating incomplete suppression of the organisms, were obtained after completion of treatment. In only one instance, in which the infecting organism was a somewhat penicillin-resistant nongroup A Streptococcus, did strongly positive cultures persist despite penicillin treatment. The bacteriological findings, then, in the "successful" penicillin-treated patients contrast strikingly with those in the two "failures" and suggest that the development of rheumatic fever in the latter patients was due to incomplete suppression of the organisms or to reinfection.

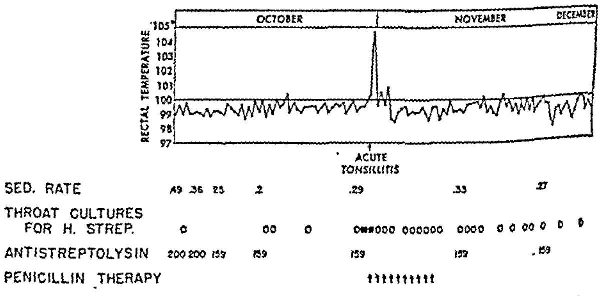

Fig. 2.—Clinical chart of a patient treated with penicillin at the time of a hemolytic streptococcic infection. This infection was not followed by an increase in rheumatic fever activity. Note prompt disappearance of streptococci from the throat flora and failure of antistreptolysin 0 titer to rise.

This interpretation, in turn, raises a question, which may be of practical importance but which cannot be answered without further study: Could the two instances of rheumatic fever recurrence have been prevented by more effective penicillin treatment (larger oral doses or intramuscular therapy), by treatment for longer than 10 days, or by the administration of penicillin to the other members of the house so that reexposure and reinfection might be prevented?

---

[7] Drs. Rebecca C. Lancefield and Stuart D. Elliott of the Hospital of the Rockefeller Institute assisted in the identification of the type 2 strains.

THE ANTISTREPTOLYSIN O RESPONSE

One of the toxins produced by hemolytic streptococci is an oxygen labile hemolysin known as streptolysin O. This substance is antigenic and, when released during streptococcic infection, stimulates the production of an antibody called antistreptolysin O. In the course of the present study a sufficient number of blood samples were obtained from 10 of the patients with untreated infections and from 27 of those with penicillin-treated infections, to allow for an accurate determination of the response of the antistreptolysin 0 titer.

Table 5, in which these observations are recorded, shows that a significant rise in titer (two tubes or more) followed all 10 (100%) of the untreated infections but only 10 (37%) of the penicillin-treated infections. A rise of four tubes or more was observed in nine (90%) of the untreated infections and in only four (15%) of those in which penicillin was administered. These data suggest that penicillin therapy of hemolytic streptococcic infections suppresses the antistreptolysin O response. Similar observations have also been made by other investigators.[8]

TABLE 5.—*Antistreptolysin O Response in 27 Infections Treated with Penicillin and in 10 Infections Not Treated with Penicillin*

Maximum Increase [illegible]	0	1	2	3	4	5	6	7	8	9	10	Total Infections
Untreated infections	0	0	1	0	2	4	1	0	0	1	1	10
Penicillin-treated infections	14	3	4	2	2	1	1	0	0	0	0	27

* The antistreptolysin 0 test is so set up that the difference in the logarithms of the absolute titers in any two adjacent tubes is equal to 0.10.

The antistreptolysin O response, or, for that matter, the development of any other antibody, has not yet been definitely implicated in the mechanism by which rheumatic fever is precipitated by hemolytic streptococcic infections. Nevertheless, the fact that penicillin therapy can interfere with the elaboration of an antigen sufficiently to influence the antibody response is perhaps significant and suggests that this therapy similarly may interfere with the elaboration of the unknown streptococcic substance responsible for the production of rheumatic fever.

SIGNIFICANCE OF FINDINGS IN RELATION TO GENERAL PROBLEM OF RHEUMATIC FEVER PREVENTION

The problem of rheumatic fever prevention can be divided into two phases. The first is concerned with the prevention of recurrences; the second involves the prevention of initial attacks of the disease.

It is well known that rheumatic fever is a repetitive disease [9] and that with each new episode the degree of cardiac damage may be increased. Furthermore, the mortality from first attacks of rheumatic fever is relatively low, most deaths from rheumatic heart disease, at least in children and young adults, being traceable directly to recurrences of active rheumatic fever. Hence, anything that can be done to reduce the incidence of such recurrences should contribute toward the lowering of the mortality from and the reduction of the crippling effects of this disease.

The data that have been presented suggest that prompt and adequate penicillin therapy of hemolytic streptococcic respiratory infections in rheumatic subjects may be effective for this purpose. At the same time attention should be directed to the fact that approximately 40% to 50% of rheumatic episodes result from hemolytic streptococcic infections with which there are associated no fever or other clinical manifestations or in which symptoms are so mild that they are overlooked.[10] Obviously such infections, not being clinically recognizable, could ordinarily not be treated with penicillin and, therefore, even if prompt penicillin therapy of clinical hemolytic streptococcic infections should prove to be effective for rheumatic fever prevention, the maximum reduction in risk that could be expected by the method would be 50% to 60%.

Therefore, for childen and young adults who have had one or more previous attacks of rheumatic fever an attempt to prevent, in the first place, the development of all hemolytic streptococcic infections, subclinical as well as clinical, would seem to be a method of prophylaxis preferable to one which depends on the treatment of already developed infections. That the continuous daily administration of sulfadiazine or other sulfonamide in small doses may be useful for the prevention of streptococcic infections, and hence for the prevention of rheumatic fever recurrences, has already been demonstrated,[11] and data are now accumulating which suggest that daily oral penicillin may be even more effective for this same purpose.[12]

The second phase of the problem of rheumatic fever prevention is concerned with initial attacks of the dis-

ease. If penicillin treatment of hemolytic streptococcic infections suppresses the growth of streptococci in the upper respiratory tract sufficiently to reduce the elaboration of the unknown rheumatic fever-producing substance to subeffective levels in persons who have previously had one or more attacks of rheumatic fever and who are presumably unusually vulnerable to the disease, it seems reasonable to expect that similar treatment would have a similar effect in persons who are susceptible to rheumatic fever but who have not yet had an attack. The validity of this inference is supported by the recent report of Denny and co-workers,[13] who observed *in an air force training base only two cases of definite* rheumatic fever in 798 young men with streptococcic infections treated with penicillin in contrast to 17 definite attacks of the disease in 804 untreated patients. On the other hand, Weinstein and his associates [14] observed rheumatic fever in 12 (7%) of 167 scarlet fever patients treated with penicillin and concluded that "the treatment of scarlet fever with crystalline penicillin G does not prevent the development of rheumatic fever."

Although these latter studies raise some doubt about the value of penicillin therapy of streptococcic infections for rheumatic fever prevention, attention should be called to the fact that most of Weinstein's cases of rheumatic fever were extremely mild and in many the diagnosis rested on slight changes in serial electrocardiograms. The extreme mildness of the disease process in these patients is indicated especially by the fact that in all but one the sedimentation rate was not elevated, a finding which contrasts strikingly with our experience at the House of the Good Samaritan, where, except in the presence of congestive heart failure, normal sedimentation rates in patients with other clear evidence of active rheumatic fever have been observed rarely. Even if Weinstein's criteria for rheumatic fever are accepted, the possibility must be considered that the incidence of a similar mild rheumatic process would have been a great deal higher than 7% in his scarlet fever patients had they not been treated with penicillin.

From the foregoing discussion it is evident that further observations will be necessary before any final conclusions can be drawn regarding the value of treating hemolytic streptococcic infections as a method for preventing initial attacks of rheumatic fever. Nevertheless, the available data are sufficiently suggestive to warrant optimism about the results which will be revealed by further studies.

SUMMARY AND CONCLUSIONS

Rheumatic fever recurrences in rheumatic subjects developed after only two out of a total of 34 hemolytic streptococcic infections in which penicillin therapy was begun promptly and continued for 10 days. In contrast, there were six instances of rheumatic fever following 12 similar infections in which penicillin therapy was not used. The administration of penicillin also appeared to suppress the antistreptolysin 0 response in many cases. These observations suggest that prompt and adequate penicillin therapy of hemolytic streptococcic infections in rheumatic subjects is effective in reducing the incidence of rheumatic recurrences. However, because of the relatively small number of cases involved in this study and because of the variety of serological groups and types of streptococci associated with the infections, final conclusions are not yet warranted. The observations also support other investigators' studies which suggest that the incidence of initial attacks of rheumatic fever can be reduced by penicillin therapy of clinical streptococcic respiratory infections. Prompt penicillin therapy of streptococcic infections is not recommended as a substitute for the use of continuous prophylactic measures in persons who have had one or more attacks of rheumatic fever.

RHEUMATIC HEART DISEASE IN PATIENTS OVER SIXTY YEARS OF AGE

Major S. Baer Appel (MC), U.S.A.
and
Charles E. Kossmann, M.D., New York

Rheumatic fever and rheumatic heart disease are usually considered to be diseases of the young. The average age of onset of rheumatic fever has been calculated in several series of cases with rheumatic heart disease. In 3,129 deceased patients studied by Cohn and Lingg [1] it was 14.5 ± 0.3 years for males and 15.0 ± 0.3 years for females; in 644 patients observed by De Graff and Lingg [2] it was 17 years; in 1,042 children observed by Wilson and Lubschez [3] it was 6.5 years. There are reports, however, of initial episodes of rheumatic fever in the seventh decade.[4] Among 3,741 patients with rheumatic fever entering Bellevue Hospital from 1911 to 1919, Lambert [5] found 91 over the age of 60.

Older data on the duration of life after the initial manifestation of rheumatic fever in the course of rheumatic heart disease indicate a poor prognosis. Cohn and Lingg [1] found the mean duration of life to be 13 years; De Graff and Lingg,[2] 15 years. In contrast to these, Wilson and Lubschez's study [3] demonstrated that the median duration of life for rheumatic children (with cardiac involvement) is greater than 30 years after onset. The discrepancy between the first two reports and the last is

---

This article has been shortened for publication in THE JOURNAL by omission of tables 1, 2, and 3. These will appear in the authors' reprints.

From the Department of Medicine, New York University College of Medicine; the Adult Cardiac Clinic and wards of the Third (New York University) Medical Division, and the Pathological Laboratories of Bellevue Hospital.

attributable to the selection of different groups of rheumatic patients. As Swift and Cohn[6] noted:

> . . . De Graff's cases, from Bellevue Hospital, were originally chosen because they had reached the stage in their cardiac career where they had symptoms of cardiac insufficiency from which they subsequently died; rheumatic children who died early as well as those who later did not develop cardiac symptoms were not included.

The latter constitute possibly 30 to 50 per cent of young rheumatic cardiac patients.[7] They would also be excluded from studies such as reported by Wilson and Lubschez and by Cohn and Lingg. Heart disease in them is usually discovered by routine thoracic x-rays and by physical examinations made for some other purpose. In some the discovery of gross rheumatic lesions is an incidental finding at necropsy.[8] Microscopic evidence of rheumatic cardiac lesions is even more often an incidental finding, the frequency depending somewhat on the pathological criteria for rheumatic disease used.[9]

Although the average duration from onset to termination of rheumatic heart disease is relatively short, there are extremes on either side of the mean. Some patients die in heart failure during their first bout of rheumatic carditis or within a decade of its onset. Others recover, have no recurrences, and survive for 40 years or more with valvular disease; they ultimately die of an unrelated disease without ever having had myocardial insufficiency.[10] Isolated cases with an interval varying from 54 to 63 years between the initial attack of rheumatic fever and the final clinical observations have been reported.[11] In one series of 12,000 patients[1] there were 75 who died at 60 years of age or over, and 25 patients over 60 years of age were still living at the time of the report.[12]

White and Bland[13] explained the benign clinical course of rheumatic heart disease with long survival on the basis of (1) a relatively mild degree of mitral stenosis; (2) the development of rheumatic heart disease in later life; (3) the relatively quiet, careful mode of living, and (4) probable ancestral longevity. Other reasons for longevity often given are the development of hypertension (Baker and Musgrave,[4] and Cookson[14]); the infrequency or mildness of recurrent rheumatic activity (Cohn and Lingg,[1] Baker and Musgrave,[4] and Wilson[15]); the absence of atrial fibrillation (Cookson[14] and Kossmann and Connor[16]); involvement of the mitral valve to the exclusion of other valves (Cabot[17]); the presence of chorea as the sole rheumatic manifestation (Cohn and Lingg[1]).

The present study was undertaken for three reasons: (1) to find, if possible, the causes for longevity in a selected group of patients with rheumatic heart disease and over 60 years of age; (2) to learn what clinical data, if any, might be of use in recognizing rheumatic heart disease so often overlooked in the aged; (3) to dispel the common clinical notion that advanced age and rheumatic heart disease are incompatible.

METHODS

The 71 patients in the study were observed in the Adult Cardiac Clinic and on the wards of the Third Medical Division of Bellevue Hospital. A few were private patients seen in consultation. Criteria used in their selection were (1) the presence of clinical or necropsy evidence of gross rheumatic heart disease; (2) age of 60 years or over at the time of the last observation or at the time of death.

The criterion used in the clinical diagnosis of rheumatic heart disease was the finding of physical and laboratory evidence of a characteristic structural lesion in the heart.[18] In all but four this "characteristic" structural lesion was mitral stenosis with or without other valvular disease. In the four exceptions there was clinical evidence of aortic valvular disease alone (cases 7, 12, 19, and 28), a good history of rheumatic fever, and discovery of heart disease in three early in life. In 48 patients there was a history of rheumatic fever; in all but 6 one of the major manifestations, namely polyarthritis, chorea, or carditis, had occurred. The pathological criteria for rheumatic disease, present in all of the 20 patients who came to necropsy, were those defined by de la Chapelle, Graef, and Rottino.[19] Actually, 14 of these were included in the report made by these authors.

RESULTS

Clinical and Pathological Results.—The case summaries have been arranged in three groups, each in the order of decreasing age of the patients. The first includes 36 patients alive at last observation (table 1); the second includes 15 patients who died but did not come to necropsy (table 2); and the third includes 20 patients who came to necropsy (table 3). Table 4 is an over-all summary of the three groups.

Six patients in the series had rheumatic heart disease for 60 years or longer. Four of these were alive and well at last observation. One patient (M.Do.), 80 years of age, had chorea and "irregular heart action" at the age of 14, and polyarthritis at 22 and 31 years. She had nine normal pregnancies and one miscarriage, and is still physically active.

In 48 patients (68%) in whom there was a history of a rheumatic manifestation in the past (carditis, polyarthritis, chorea, scarlet fever, or "rheumatic fever"), the average age of onset was 21.5 years; the average age at time of death or at the time of the last clinical observation was 66.9 years, and the mean duration from the onset of rheumatic fever to the last recorded age was 43.6 years. The average age of onset was therefore 4.5 to 15 years later than in previously reported series (Cohn and Lingg,[1] De Graff and Lingg,[2] and Wilson and Lubschez[3]), but the scatter was considerable (from 5 years to 55 years of age). Statistical proof of the significance of the difference in means of age at onset of the present series and of the series of Cohn and Lingg's deceased patients was obtained by the method of unpaired comparisons using the "standard deviation of each sample" method. The ratio (t) of the difference between the means to the standard error of this difference was 3.84 in the case of the males of Cohn and Lingg's series, and 3.57 in the case of the females. Both values are greater than the probability level of 2.6 of the normal curve ($P < 1\%$), and therefore are highly significant statistically. This means that the later mean onset of rheumatic fever in the present series was very probably a determining factor in longevity.

Ancestral longevity as a factor in determining long life with rheumatic heart disease is most difficult to evaluate. The average age of the mother was 60.7 years in 29 instances; the average age of the father was 64.9 years in 29 instances. Of the total of 58 parents, two-thirds were over 60 years of age. With few exceptions, these averages represented the age of death of the parents. There were six patients with one parent and two patients with both parents who were over 80 years of age. A conclusion from these data cannot be drawn without recourse to a lengthy statistical analysis which should include several types of control groups.

Recurrences of rheumatic fever were not inconsiderable (tables 1, 2, and 3). There were 16 patients (30% of those with a history of a rheumatic manifestation) who had multiple attacks of rheumatic fever in some form. Four had only two attacks. One had the maximum number of six; this patient (J.Ho.) was last examined at the age of 63, 31 years after the first attack (table 1). The high frequency of recurrences in the series suggests that recurrences alone were not related to longevity, although this is not absolute. Perhaps the relatively older average age of recurrences, just as the older average age of onset, was the important factor. There was, of course, no way of evaluating the significance of severity of initial or subsequent attacks of rheumatic fever.

Only 2 patients had chorea, usually regarded as a mild manifestation so far as the heart is concerned.[1] However, both of these had, in addition, polyarthritis during other attacks.

The varieties of valvular lesions were of interest particularly since it is believed by some (Levine,[10] Rothschild, Kugel and Gross,[10] Criteria Committee of the New York Heart Association [18] and Stewart and associates [20]) that certain combinations alter the hemodynamics in a favorable way. Of the 71 patients (table 6), 42 (59.1%) had mitral stenosis and insufficiency; 22 (30.9%) had combined mitral and aortic lesions; three had combined mitral and tricuspid lesions; and four had aortic disease alone. In the 20 necropsied cases none displayed aortic lesions alone (table 5). It is difficult to conclude that any one lesion or combination of lesions accounted for longevity since similar distributions occur in any age group. To be noted particularly is the paucity of patients with tricuspid stenosis (2 proved, 1 questionable), and the presence of a tight mitral valve in several (table 3, cases 4, 6, 9, 14, and 17). Although table 5 shows a smaller mean weight of the hearts with tricuspid stenosis and a larger mean weight with aortic valve disease as compared to the weight of hearts displaying mitral lesions alone, it is probable that the total number of cases of each type is too small to draw conclusions.

Atrial fibrillation is also regarded as a terminal event in the disease, although durations in excess of 20 years have been reported (Kossmann and Connor [16] and Bishop and Bishop, Jr.[21]). In the present series, 33 patients displayed this arrhythmia at some time. Of these the duration was fairly certain in 16, where it averaged five years. However, 9 patients displayed the rhythm for more than five years, and the maximum duration was 14 years. Other abnormalities encountered electrocardiographically are shown in table 6.

Only 9 patients (table 7) had a blood pressure persistently above 150 mm. Hg. systolic and 90 mm. Hg. diastolic. Six of these displayed atrial fibrillation. Hypertension, therefore, was not a frequent finding (7.9%) in the series.

A point of interest from the viewpoint of differential diagnosis was the mean duration of diminished cardiac reserve (table 4) which in 51 patients was 12.2 years (maximum 53, minimum 0). The mean duration of life after the first bout of heart failure was 7.9 years (maximum 30, minimum 0). It was the impression that these relatively large values would be helpful in suspecting the disease clinically. To this end a comparison was made with similar values determined in a group of 138 patients with degenerative (hypertensive and/or arteriosclerotic) heart disease. These lived on the average 1.8 years after the appearance of the first evidence of congestive heart failure, although 24% were alive three years after.[22] These figures would seem to substantiate the clinical impression that rheumatic heart disease is to be suspected when the course is characterized by prolonged cardiac disability.

It was not possible to determine the causes of heart failure in the group. In this regard the hearts of only three patients displayed evidence of rheumatic activity at necropsy.[6] This was out of a total of 12 which were examined microscopically. This is comparable to a recently reported series of elderly rheumatic cardiacs[23] in which four of 16 patients over 60 years old showed lesions of rheumatic activity at necropsy.

A point of considerable clinical interest is that the diagnosis of rheumatic heart disease, particularly of mitral stenosis, was missed during life in eight of the 20 patients who came to necropsy (table 3).

Electrocardiographic Results.—The standard leads were available in 58 patients, precordial leads in a few, and intracardiac leads in one. The findings are summarized in table 6. Of greatest interest is that only five of the 58 displayed right deviation of the axis of QRS (angle alpha greater than + 90 degrees or less than — 90 degrees), and only two displayed right bundle branch block (patients M.Ca. and S.Pa.). One patient (F.Mc.) who displayed a right ventricular wall 1.2 cm. thick at necropsy, showed a right deviation of the mean axis of QRS, and a low voltage rsR′ in the lead from the right sternal edge but the QRS interval was 0.08 sec. An insufficient number of precordial leads were available in other cases to make any further statements about them. It is often stated that disease of the mitral valve among other things should be suspected in older patients if the electrocardiogram displays right deviation of the electrical axis of QRS. This is probably true but the present electrocardiographic observations indicate that the diagnosis will be missed in the majority of older patients with rheumatic mitral stenosis if too much reliance is placed on this finding.

longevity and of noting any manifestations which might make the clinician suspect the presence of the disease.

Of those possible factors in longevity which could be analyzed, including the degree of mitral stenosis, ancestral longevity, accompanying hypertension, infrequent recurrences of rheumatic fever, absence of atrial fibrillation, univalvular involvement, and late age of onset of rheumatic fever, only the last seemed to be a statistically valid factor in determining long life with rheumatic heart disease.

The mean duration of diminished cardiac reserve in 51 patients was 12.2 years; the mean duration of life after the first bout of congestive heart failure was 7.9 years. Therefore, the disease should be suspected in elderly patients when cardiac disability persists over a period of years.

The high incidence (40%) of missed diagnoses in the group of 20 patients that came to necropsy suggests that the incidence of rheumatic heart disease in the aged is far greater than available data indicate.

FAILURE OF TONSILLECTOMY

T. L. Hyde, M.D., The Dalles, Ore.

Tonsillectomy is the commonest surgical operation, constituting about one-fourth of all operations performed. It is the operation that is done by more different physicians than any other. It is not usually a successful operation, however, because residual tonsil tags were found in 68% of 1,000 tonsillectomized patients. Better results can be achieved by improvement of the technique of the operation.

THE STUDY

One thousand patients were observed consecutively without selection in a general surgical practice over a period of years. Every patient who had had a tonsillectomy was interrogated and examined. They were asked (1) their age, (2) the age at tonsillectomy, (3) where the operation was done, (4) whether the surgeon was a "nose and throat" specialist, (5) why the operation was performed, (6) what anesthetic was used, (7) whether any benefit was obtained, and (8) whether to their knowledge any tonsillar tissue was left. Then the pharnyx was carefully examined with the use of a good light, a metal tongue depressor, and a tonsil pillar retractor. The tonsil tags were recorded as grade one to four, grade one being the smallest and grade four being an amount comparable to a normal size tonsil. The presence of lymphoid tissue not identifiable as tonsil tissue was also recorded.

THE RESULTS

Sixty-three per cent of the 1,000 patients were women. The average age was 36; the average age at operation was 19. Sixty patients had had two operations, and three had had three tonsillectomies. Only 240 thought that their surgeon was a specialist. Geographically the operations were performed mostly in the Pacific Northwest and near Texas. Sixty per cent of the operations were done with the patients under general anesthesia. Nineteen per cent thought their tonsils had been removed to improve their general health, and the other 81% because of local throat disorders. Thirty-one per cent denied any beneficial effect from the operation. Forty-two per cent of those expecting to have their general health improved denied receiving any benefit. Among those denying benefit, the incidence of retained tonsil tags was no greater than among those claiming benefit from the operation. The indications for tonsillectomy as revealed by this group of patients were very broad. This part of the study, of course, is largely subjective and probably is merely interesting and not valid scientific evidence justifying any conclusion regarding tonsillectomy.

Objectively, 68% of the patients had tonsil remnants, and only 32% had had a complete tonsillectomy. Of the 2,000 tonsil fossae examined, 1,120, or 56%, had tonsil tags. Forty-nine per cent of these tags were grade one, 29% were grade two, 14% were grade three, and in 8% the remnants were as large as a normal tonsil (grade four). Thirty-three per cent of the 1,000 patients had lymphoid tissue not identifiable as tonsil tissue. Among the 32% with no tags, some lymphoid tissue was found in the tonsillectomy scar area in 26%. Only 20% of the patients had throats that were absolutely clear of all lymphoid tissue in the palatine tonsil area. Only 20% of the patients with tags were aware of their existence. One per cent of those with clean throats thought they still had some retained tonsil tissue. Among the 400 patients who had had a local anesthetic, only 59% had tags. This would appear to be a significant difference in favor of a local anesthetic but may merely reflect the comparative ease of operative procedure in the larger throats of an older age group. Among those who believed their surgeon was a specialist, 64% had retained tags, a percentage that is not impressively better than the general average.

THE LITERATURE

These results are consistent with other similar studies. Gooch and Lillie [1] of the Mayo Clinic have recently published an excellent study of tonsil tags. They found an incidence of 22% of tonsil tags among the patients who had had a tonsillectomy prior to registration at the clinic. Sputh and Sputh [2] reported an incidence of 80% of tags among 285 patients. Kaiser [3] found an incidence of 38% in 1,000 school children. He also observed the incidence of otitis media, sore throats, and other diseases commonly associated with chronically infected tonsils to be increased in those with incomplete operations. His classic work is the only study found of the effect of tonsillectomy that considered the factor of incomplete operation.

Read before the Annual Meeting of the Oregon State Medical Society, Gearheart, Ore., Sept. 27-29, 1950.

[1] Gooch, J. O., and Lillie, H. I.: A Clinical and Pathologic Study of Tonsil Tags, Ann. Otol., Rhin. & Laryng. 57:957 (Dec.) 1948.

[3] Kaiser, A. D.: Results of Tonsillectomy, J. A. M. A. 95:837 (Sept. 20) 1930.

Lüscher[4] noted an incidence of 22% in 224 patients he had operated on himself. Campbell[5] observed an incidence of 77% in 631 tonsillectomized university students. McLaggan[6] reported an incidence of 49% in 100 school children. He titled his article "A Plea for More Careful Tonsillectomy." Rhoads and Dick[7] found an incidence of 73% among a group of 403 nurses. Clark[8] in 1913 reported 43% among 143 patients operated on at the Massachusetts General Hospital. Coues[9] reported in 1910 an incidence of 30% in 40 school children.

The variation in the percentage of tags found by the various reporters is probably due to variation in the criteria for identification of a tonsil tag. Gooch and Lillie[1] reported that otolaryngologists found half again as many tags in a given group of clinic patients as had the general diagnosticians. McLaggan only considered fragments as large as one-fourth of the tonsil. Most reporters did not discuss their criteria. In this study the presence of a crypt in a mass of lymphoid tissue in the tonsillectomy scar area was taken as the identifying characteristic of tonsil tissue. The single characteristic that distinguishes the palatine tonsil from the other lymphoid tissue of the pharynx is the crypt. Lymphoid tissue of the adenoid or lingual regions does not contain crypts. Inflammation often facilitates identification by accentuation of the crypt. It is probable that some of the patients reported to have lymphoid tissue actually had tonsillar remnants. None of the other reporters distinguished between lymphoid tissue and tonsil remnants.

The patients themselves usually assumed that their tonsils had "grown back." I have never observed any such regrowth. Most of those who have studied the problem agree that tonsils do not recur.[10] Some[11] have remonstrated that all the extra capsular lymphoid tissue of the tonsil area cannot possibly always be removed. It is probably true that there is commonly considerable extra capsular lymphoid tissue. This peritonsillar lymphoid tissue probably is not tonsil tissue.[12] However, my own careful dissections have demonstrated the frequent existence of irregular rounded lobules of tonsil 2 to 20 mm. in diameter extending out beyond the so-called capsule into the peritonsillar tissue. These parts of the tonsil can easily be left in place by rough, careless dissection. Some tags probably represent such lobules left in place. Most of the tags are at the top or bottom of the tonsil and are plainly bits of the visible tonsil not disturbed by crude dissection with blunt instruments and snares.

THE TECHNIQUE

The operation of tonsillectomy for some obscure reason, probably based in antiquity when the tonsil was removed with the fingers without anesthesia, commonly seems to be considered in a category all by itself. Apparently it is immune to the considerations that govern other surgical procedures, such as good exposure, meticulous hemostasis, and careful dissection. Most physicians who remove tonsils are enthusiastic about their operation whenever they are given an opportunity to describe their method. Usually the enthusiasm is for the "slick," "easy," or "quick" method they have adopted. An occasional exception is the competent surgeon who usually admits he finds the operation difficult and time consuming. The 680 patients with tags probably were subjected to a great variety of operative methods, all of which had one thing in common: failure to remove all the tonsil. Certainly a fair test of an operation is that it should accomplish what it intends to do, and such a high incidence of tags following tonsillectomy is *ipso facto* evidence of failure. Irrespective of any consideration of the indications for tonsillectomy and its possible benefits, if the operation is to be done, it is reasonable to expect that the tonsil shall be removed. Most of the justifications for tonsillectomy must be based on complete removal.

It should be legitimate to compare tonsillectomy with the operation for excision of a branchial cleft cyst commonly situated nearby, for example, 1 cm. closer to the skin. They are usually approached with different attitudes however. The difference is that complete excision of the branchial cleft cyst is assumed as a matter of course, whereas portions of the tonsil are usually left in situ. For instance, no surgeon would think of using a snare on a branchial cleft cyst.

Tonsillectomy has certain inherent factors that make it a very difficult operation. The exposure is limited by the size of the mouth, and one cannot improve the exposure by getting an interne to hold a retractor. Illumination can only come from one direction. Hemostasis is difficult because of the small size and depth of the avenue of approach. It is necessary to use long clamps and tie knots at finger tip depth. Moreover the usual position of the patient during operation causes the blood to collect in a pool at the line of dissection. Often the blood runs down the throat causing the patient to gag and cough or arousing apprehension of pulmonary complications.

None of these inherent factors is insurmountable if the surgeon is determined to remove all the tonsil and is willing to take the time and pains to do it by applying the usual standards of any good operation. The position of the patient can be made to facilitate the operation rather than hinder it. For the patient under general anesthetic, the Davis type of mouth gag allows the head to hang inverted over the end of the operating table. The surgeon sits in front of the open mouth. The blood of any uncontrolled bleeding runs down into the nasopharynx and out the nose. The head mirror provides the best illumination, after the surgeon acquires the skill to use it. Intratracheal intubation is sometimes desirable for older patients with stiff necks. One begins the dissection with a sharp knife by outlining the tonsil, including all visible tonsil tissue, especially at the junction of the tonsil and tongue. The tonsil edge is grasped with a tenaculum at the lowest part, which anatomically is designated the superior pole. The dissection proceeds upward and backward by sharp snips with scissors. The line of dissection is always clear, because the blood runs downward and away from it. Spurting arterial bleeding may occasionally jet upward to obscure the line of dissection, and such bleeding is controlled by clamp and tie as in any other operation. The clamp can be applied and left dangling until the dissection is complete. The Sten clamp with the jaws curved at 45 degrees seems most convenient. The tie is made with a 20 in. strand of no. 20 crochet cotton thread. No assistant is necessary. The dissection by scissors is carried completely through to the base of the tongue. No snare is used. There is no reason for one end of the tonsil being dissected any differently from the other end. In fact, the inferior (lingual) pole, which is so often "dissected" by a snare, is more apt to have irregular lobules which require the most careful dissection by scissors for clean removal.

The patient under local anesthetic is seated on an operating table, which is arranged with the foot down and the back up to form a chair. The "knee strap" is tightened across the lap so the patient can lean forward against it. The table is raised to full height. The surgeon sits in front of the patient, who leans forward so the mouth opens downward. The lamp for the head mirror is above the patient, and the surgeon looks upward into the patient's mouth. Blood and saliva drain downward and out of the mouth rather than into the pharynx. After anesthetic infiltration, the dissection is begun by an incision as above described, all the tonsil tissue being outlined. The tenaculum grasps the tonsil at the lower anterior part, at the junction of the anterior pillar and the tongue. The dissection proceeds upward and backward with no opportunity for the blood to collect in a pool at the line of dissection. In this position, each tonsil can usually be removed without the patient's coughing or gagging, except for an occasional spurting artery which may jet across into the pharynx.

RESULTS OF OPERATIVE PROCEDURE

Two hundred sixty-two patients have been operated on in such a manner with a purposeful effort to remove all the tonsil and have been observed six months or more later. The throats of 48 patients (18%) showed some lymphoid tissue in the tonsil area, but in only two of them could the lymphoid tissue be identified as a remnant of tonsil.

SUMMARY

The operation of tonsillectomy as ordinarily performed is considered to be a failure as evidenced by 68% of tonsil tags in a group of 1,000 tonsillectomized patients. Careful dissection, which is facilitated by described technical methods, especially the position of the patient, has been successful in 99% of 262 patients.

PROBLEMS OF THE GERIATRIC ASTHMATIC AND THEIR CLINICAL MANAGEMENT

Louis Tuft, M.D., Philadelphia

It has been truly said by Stieglitz [1] that old age begins at birth and can be terminated only with death and also that aging is part of living. The recent interest in the study of older or aged people has created the specialty of medicine known as geriatrics, which concerns itself with the physiologic, pathologic, and clinical problems of the elderly. Its need has been stimulated by the remarkable recent increase in the number of older people, brought about largely by the prolonged life span resulting from advances in preventive medicine and therapeutics. As a consequence, many more people now live to 65 or 70 or older and physicians, therefore, must treat many more older people than formerly.

Geriatrics, in a sense, is the converse, or mirror image, of pediatrics and in certain respects is confronted with similar problems. Thus, for example, just as infancy is a critical period in pediatrics, so too is the period of later maturity (between 40 and 60) a critical one for the geriatric patient because of the greater incidence of progressive and degenerative diseases; and since such a patient is an adult growing older, he is also subject to the same diseases and conditions as when younger. Geriatrics therefore embraces many different specialties of medicine: Allergy can and does affect the older person and there is no good reason for assuming that it should not. Hay fever, urticaria, asthma, or atopic dermatitis can begin in people past 40, although less frequently than in younger persons. Asthma, for example, may begin in a person past the age of 75.[2] Recently I saw a 77-year-old patient with typical allergic bronchial asthma which began at the age of 74 and which responded satisfactorily to the usual allergy treatment. For some time, it has been generally considered that allergic conditions rarely begin in senescence or senility and that when they do arise at that time other factors must be operative. This was especially true for asthma. Thus, according to Alexander,[3] asthma is a disease of early decades. He cites the statistics of Coke,[4] who in 1927 found only 20 patients, or 2% of a series of 1,000 asthmatics, to be over 60. The only comparable statistics available at present are those of Rowe and Rowe [5] in 1947. While

these authors did not particularly compute the incidence of asthma in older persons, they mention in their article that of a total of 1,232 private patients there were 72 whose asthma began after 50. This is an incidence of 5.85% and undoubtedly would be higher if only those whose asthma began after 40 were included. Likewise, Fuchs[6] in 1947 reported that, of 200 asthmatics studied, the age of onset at the initial attack was given as past 50 in 27, or 13.5%. This increase in incidence may occur because people are living longer or because physicians are seeing more of them. Despite this, however, some older ideas concerning incidence and etiology in the geriatric asthmatic still prevail, at least as judged by a review of current books and of the sparse literature on geriatrics. It seems worthwhile, therefore, to review this subject, discussing in particular questions of etiology, differential diagnosis, and clinical management. Discussion will concern those patients whose asthma began after midlife and not those who are past 40 and have asthma regardless of when it began. If a patient of 50 has had asthma since he was 20 or 25, the problem of etiology, diagnosis, and management may be quite different from that of a patient of the same age with asthma of only one or two years' duration. Recent articles on this subject by Cueva[7] and by Rowe and Rowe[5] refer to patients past 50 who have asthma regardless of when it started. While their reports are helpful regarding incidence, complications, allergic aspects, etc., they do not differentiate between asthma beginning in the geriatric patient and that beginning before 40.

ETIOLOGY

In the etiology of asthma in the geriatric patient, as contrasted with the younger patient, a difference is observed in the importance of the factor of heredity. Cooke and Vander Veer[8] showed that the significance of hereditary predisposition to asthma decreased progressively after the age of 20. This seems to be verified by clinical experience. Thus, for example, asthma in older people usually is not accompanied with such marked sensitivity to specific allergens as in younger persons, nor is it associated so often with other atopic manifestations such as hay fever, migraine, or eczema. Furthermore, attacks in the geriatric generally are milder, with less tendency toward the explosive acute reactions seen in younger asthmatics, especially in those with strong atopic backgrounds.

Since heredity is not important in predisposing the older person to asthma, the initial attacks may result either from acquired sensitization to inhalants, foods, drugs, or bacterial allergens or from internal causes (endocrine or psychosomatic); the asthma thus provoked may well be the starting point for a new line of allergic offspring in subsequent generations. Undoubtedly older as well as younger persons can be sensitized to inhalant allergens, as, for example, to various occupational dusts. But the extent of exposure required is an undetermined variable which probably depends upon such factors as tissue or cell reactivity, about which relatively little is known. Nevertheless, asthma may be acquired by older persons by contact with environmental allergens; and, as a corollary, exposure to such contacts may be a potent factor in the development of the asthma.

Development of allergy to foods by older persons from continued exposure is less likely than is the case with inhalants. Experience with children has shown that continual ingestion of allergenic foods will sometimes bring about sufficient improvement in tolerance to enable them to eat these foods in average or larger amounts. Therefore, except in exquisitely sensitive patients, many food allergies will be overcome during maturity. Whether allergies to new foods or overindulgence in foods to which they formerly were allergic may be responsible for the food allergy in these persons is difficult to ascertain. Opinion is divided chiefly because most of the evidence is based upon the results of skin tests rather than diet trial. Nevertheless, clinical experience indicates that food allergy may be important in some geriatric asthmatics and its disregard may explain some treatment failures.

Despite these variations, the development of asthma in the geriatric patient and the mechanism of reaction are essentially similar to those of the younger person with one important difference. It has been emphasized unduly by some authors, leading to considerable misconception of the origin of the asthma and often to unnecessary treatment. This is the idea to be found in some textbooks on geriatrics,[9] and also in the publications of some allergists to the effect that asthma developing past midlife is almost always intrinsic or infectious in origin. This thought is so firmly entrenched in the minds of many that if a patient past midlife presents himself with asthma of fairly recent orgin it is assumed at once that the asthma is of infectious or intrinsic origin. For example, Rackemann in a recent article[10] concludes that asthma beginning after age 40 is not often due to allergy but is caused by something which the patient carries with him at all times. He considers infections in the respiratory tract, either primary or secondary, highly important; also, more general disturbances of the whole body, especially emotional or psychosomatic factors, in addition to physical disturbances such as focal infections, malnutrition, or poor general health from any cause. He bases these conclusions, especially as to the psychosomatic factors, upon the results of psychotherapeutic treatment, including reassurance to allay fear, and also upon the fact that "death from asthma can occur from nothing more than emotional strain."

These statements are subject to challenge since they are contrary to the clinical experience of many others. As I pointed out several years ago,[11] the term "intrinsic" or "infectious" asthma often is used when the cause of the asthma is unknown. It should be replaced by the more descriptive term "idiopathic," which describes the situation more accurately. Regardless of these considerations, however, it is difficult to understand why asthma in a patient past 40 must necessarily be regarded as infectious in origin. What it is that makes 40 or 50 or any age the dividing line between infectious and noninfectious asthma is difficult to comprehend.

Hay fever and other forms of allergy can and do begin in persons in the sixth, seventh or eighth decades; why should not asthma of nonbacterial origin? Infections generally occur more frequently in young children than in adults; yet it is agreed that "infectious asthma" is less frequent in children than in older persons. Why, then, assume that asthma beginning in the geriatric necessarily must be infectious?

One explanation may be that positive skin reactions are less frequently seen than in younger persons. This is partly true, if only moderate or marked positive reactions are considered. But since skin reactivity is lessened in older persons, doubtful or slight reactions may be as significant as larger reactions in younger persons. This is even truer of foods, for, as in younger asthmatics, skin reactions may be negative despite the existence of proved clinical food allergy.[5]

Another reason for assuming the infectious nature of asthma in older persons is the presence of evidence of sinus disease (chiefly revealed by x-ray) or of a history of frequent "colds." The fallacy of the former is obvious, since various studies, especially those of Bullen [12] and of Kern and Schenck,[13] have shown that the presence of sinus disease as determined solely by x-ray examination cannot be taken either as a reliable index of infection or as proof that the asthma is infectious. This is true also of the history of repeated "colds." These often actually represent attacks of allergic rhinitis which are mistaken for colds. Many patients with asthma beginning in later life have a history of long-standing recurrent nasal difficulties which upon detailed history and examination prove to be allergic rhinitis. Sometimes the nasal symptoms extend as far back as early maturity or even into childhood and recur only at intervals thereafter or persist in varying degree until the onset of asthma in later years. Not infrequently these patients give histories either of various nasal operations or of recurring nasal polyps, the removal of which provided relief for varying periods. Detailed inquiry into the history often will furnish ample evidence that the asthma was preceded for months or years by an unrecognized allergic seasonal or perennial rhinitis of varying severity. When seasonal, and especially in patients with hay fever of long duration or starting in later life, the initial complicating asthmatic attack may develop in the geriatric period.

It may be concluded, therefore, that there is insufficient evidence to show that asthma in the geriatric patient is necessarily or frequently infectious in origin. Inhalants such as house dust, feathers, pollens, and molds can be important offenders, since many patients with asthma of recent duration improve remarkably after change of environment. Recently a 68-year-old patient with asthma of two years' duration entered the hospital. Within 24 hours after admission, and without treatment, the asthma cleared up spontaneously. He changed residences and remained symptom-free even after his discharge 14 days later, except when he returned for a short stay at his former farm residence. The asthma here, as in other similar patients, undoubtedly was due to environmental factors like those affecting younger asthmatics. Such occurrences prove that asthma due to environmental allergens such as dust or animal danders can affect a person of 70 or more just as it does one of 20. There is little reason for assuming that the asthma is infectious merely because the patient is old.

The importance of allergy to foods already has been emphasized and should be considered in all patients. While opinion as to its incidence may vary, nevertheless, unless an attempt is made to carry out adequate diet trial, it cannot be said categorically that food allergy in the older patient is relatively infrequent. Remarkable benefit sometimes follows the institution of dietary restrictions or trial as in the following case:

Case 1.—A man, aged 62, with asthma present acutely for 10 months, previously had often been subject to so-called colds and mild coughing attacks occuring mostly in the fall. He had previously been studied in another hospital because of what was believed to be bronchitis and bronchiectasis, both of which were considered upon an infectious basis. He had had a tonsillectomy during his previous hospitalization because of that possibility.

When first seen, the patient was acutely asthmatic and showed some emphysema; otherwise the examination was noncontributory. Immediate hospitalization was refused by the patient, who asked for a delay of a week or two. In the meantime, an allergy diet and also aminophylline by mouth were prescribed Iodides were not used because there was a history of an iodide rash. When he returned a week later, there was striking improvement, with little or no audible wheezing. This persisted throughout the course of his allergy studies and for the two-year period during which he was observed thereafter. He was found to be particularly susceptible to attacks after contact with cooking odors, especially from fish or bacon, or contact with house dust. He was instructed to avoid these and was also given small doses of house dust extract for purposes of desensitization.

This case illustrates the beneficial effects of an allergy diet plus symptomatic measures in a patient with severe asthma previously considered to be upon an "infectious" basis. It might be argued—and with some justification—that the striking relief which followed was not necessarily the result of diet alone, since the patient was receiving aminophylline by mouth at the same time. However, his response was so similar to that of others who were given a diet alone that one is forced to conclude that the dietary restriction or exclusion must be important in such patients. Regardless of these considerations, his striking improvement under allergy treatment, coupled with his clinical reactions to exposure to dust or to cooking odors or cold weather, so closely resembles that of the younger allergic asthmatic as to contradict effectively the original opinion that this was an infectious asthma.

Another etiologic factor considered important in geriatric asthma and believed to contribute to its intrinsic quality is a disturbance of the endocrines, especially in women. Recent work with the pituitary and adrenal hormones has shown that these may have profound influences upon asthma. But we do not know as yet whether disturbances or dysfunction of these glands may be etiologically responsible for asthmatic attacks and, if so, whether this is more prevalent in older persons. The idea that asthma in women lessens after the menopause is not substantiated by clinical experience; it gets worse in some women instead of better. Proof of the existence of an "intrinsic factor" of endocrine origin as a cause of geriatric asthma therefore still awaits confirmation.

[12] Bullen, S. S.: Incidence of Asthma in 400 Cases of Chronic Sinusitis, J. Allergy **4**: 402, 1933.

[13] Kern, R. A., and Schenck, H. P.: Relative Efficiency of Clinical and Roentgenologic Methods for Sinus Diseases Diagnosis, with Observations on Incidence of Sinus Disease: Based on Findings in 200 Asthmatics and 50 So-Called "Normals," Am. J. M. Sc. **178**: 168, 1929.

With minor variations, the specific etiologic agents responsible for asthma are essentially the same in the geriatric patient as in younger persons. If this were always remembered, the approach to etiologic diagnosis and to specific treatment in these patients would be the same as though the asthma were affecting a person of 20 instead of 60 or 70.

DIFFERENTIAL DIAGNOSIS

In the differential diagnosis of asthma in the geriatric patient, the age of the patient brings up diagnostic problems which seldom arise in children or younger adults. When an elderly patient presents himself complaining of dyspnea associated with a wheezing respiration, it must first be determined whether the condition is bronchial asthma or a condition resembling it. The dictum of Chevalier Jackson that "all is not asthma that wheezes" applies not only to foreign bodies, especially in children, but also to other obstructive chest lesions such as mediastinal tumors of neoplastic, aneurysmal, or lymphatic origin, which may give rise to similar signs and symptoms. Such tumors usually are distinguishable by the presence of associated laryngeal symptoms (stridor or hoarseness) or of unilateral wheezing, and x-ray evidence of this pathology is distinctive enough to establish the diagnosis with certainty. Pulmonary neoplasms are more difficult to diagnose, especially when associated with typical asthmatic symptoms, because it is not easy to say whether the asthma has been provoked by the neoplastic process or whether the neoplasm exists independently of the asthma. Recently I saw a 76-year-old man with typical symptoms and signs of acute asthma of three weeks' duration and with a proved bronchogenic carcinoma which resulted in his death two months later. Except for the small shadow seen fluoroscopically in the left chest the neoplastic process might have been missed, since the only symptoms and physical signs were those of acute asthma. This emphasizes the necessity for x-ray examination of the chest in all asthmatics, especially older persons, so as not to miss an early pulmonary cancer.

Another condition offering diagnostic difficulties in the geriatric asthmatic is hypertensive cardiovascular disease, particularly so-called cardiac asthma. This term is used to designate a paroxysmal type of wheezing dyspnea, usually nocturnal, which affects those people past midlife with hypertensive cardiovascular disease. It is believed to be due to a sudden relative failure of the left ventricle in a patient whose right ventricle is functionally normal. This sudden failure produces, in turn, acute pulmonary hypertension, secondary intense pulmonary emphysema, and pulmonary edema. Often there is associated precordial pain or oppression of the anginal or coronary type. During the acute attack the condition so closely resembles bronchial asthma that it may be difficult to distinguish the two conditions by examination alone. But because the patient is elderly and has had the asthmatic symptoms for a relatively short time, as well as the presence of hypertension, left-sided cardiac enlargement in varying degrees, cardiac murmurs, and evidence of impairment of conductivity in the electrocardiogram, differential diagnosis between cardiac and bronchial asthma is fairly easy. Unfortunately, however, the history and physical findings are not always typical. My experience and that of our cardiologists indicate that true cardiac asthma is relatively uncommon. Its diagnosis is made more frequently than is warranted, especially in those patients who have nocturnal asthma with mild or moderate degrees of hypertension and no significant cardiac signs. In this situation, it is not always easy to decide whether one is dealing with bronchial asthma in a patient who happens to be hypertensive or whether the asthma is the result of the cardiac lesion. If the asthma has been present for several years and there is definite evidence of allergic sensitization either in the history or from allergy studies, the diagnosis of allergic bronchial asthma is easily established. The allergist frequently sees patients past midlife, especially women, with typical allergic bronchial asthma and a coincident benign essential hypertension. Continued observation of such patients, at least in my experience, shows that the two conditions are entirely unrelated etiologically and should be managed as though they existed independently.

In patients with allergic bronchial asthma of varying duration hypertensive organic cardiac disease or coronary accidents may develop. These have no etiologic relationship to asthma, but they make treatment more difficult, as exemplified in the following case report.

Case 2.—A man aged 75, was first seen in 1939 with bronchial asthma of three years' duration. The allergic character of the asthma was estabished by a history of attacks of perennial allergic rhinitis preceding the asthma, the presence of urticaria, and specific positive skin test reactions. Despite a blood pressure reading of 170/90, the heart showed no changes at that time. Striking improvement followed allergy treatment, especially after elimination of some very old feather pillows, plus symptomatic treatment and a short course of injections of house dust extract. He remained fairly comfortable for five years without additional or specific treatment until 1944, when at the age of 80 cough, dyspnea, and precordial pain radiating down the left arm developed. Examination showed persistence of hypertension (170/90) and also signs of cardiac insufficiency. Electrocardiograms verified the presence of coronary artery disease. He was treated for the cardiac condition and despite his age improved gradually for a while. He died of cardiac failure three years later at the age of 83.

This case is remarkable from many standpoints, but it illustrates particularly the fact that coronary disease and its aftermaths can affect patients with allergic bronchial asthma without having any etiologic relation to the asthma. Designation of asthma in such a patient as "cardiac" is erroneous and could be avoided if the differentiation between true cardiac asthma and bronchial asthma were kept in mind. This also would eliminate the custom of applying the term "cardiac asthma" to attacks of dyspnea associated with cardiac decompensation or failure. Such usage is incorrect, since neither is the dyspnea periodic nor is it associated with wheezing respiration; it should be designated cardiac dyspnea, not cardiac asthma. When asthma affects patients with such organic cardiac lesions as mitral stenosis, the relationship is likely to be coincidental rather than etiologic. In such circumstances, the wheezing respiration disappears when decompensation sets in and reappears when compensation is restored.

This brings up for consideration those pulmonary conditions in the geriatric which may simulate asthma. An outstanding example is the chronic bronchitis which, usually associated with chronic emphysema, affects older people. Examination of the chest reveals numerous sibilant and sonorous rales and even a wheezing type of respiration but there is neither paroxysmal dyspnea nor any other of the signs that characterize the acute asthmatic attack. This form often is called asthmatic bronchitis or asthmatoid bronchitis.

Opinions differ as to whether asthmatic bronchitis is a form of asthma due primarily to bacterial sensitivity or, as seems more likely, whether it is entirely secondary to an infection or irritation of the bronchial tubes which causes sufficient bronchial obstruction to produce a mild asthmatic wheeze, perhaps in a predisposed subject. The wheezing usually is secondary to the cough and is more or less continual and not paroxysmal as in true asthma. Patients with asthmatic bronchitis have little or no difficulty in sleeping in a flat position at night, in contrast to the orthopnea of those with paroxysmal or acute attacks of asthma.

Although chronic bronchitis may be due to various causes, a condition frequently responsible for wheezing respiration is pneumonoconiosis, especially the form known as "miners' asthma" (anthracosis). Such patients, after long-continued exposure (more than 12 years) to coal dust, begin to show evidence of bronchial irritation. The frequent more or less continuous attacks of bronchitis are followed by dyspnea upon exertion, with or without wheezing respiration. The latter is the last to appear and is often mild compared with the cough and expectoration. At this stage, emphysema, bronchiectasis, or pulmonary fibrosis are evident. A history of exposure to occupational dust as well as the presence of bronchitis for a long time before the onset of wheezing, together with the physical and x-ray findings, usually are sufficient to differentiate the wheezing of pneumoconiosis from that of true allergic asthma.

Presence of wheezing dyspnea in persons past middle life, usually with moderate or marked emphysema; predominance of protracted cough accompanied with little or no dyspnea in spite of signs of wheezing in the chest; presence of mucopurulent sputum, and absence of any evidence of allergy either in the history or by special examination are all of differential diagnostic importance. They serve also to distinguish asthmatic bronchitis from the bronchitis present during or at the end of an attack of allergic asthma.

Although these conditions always have been considered as instances of primary chronic bronchitis with secondary asthmatic symptoms or as nonallergic asthmas, it is not unlikely that the asthmatic wheezing associated at times with certain obstructive or nonobstructive chest conditions (e. g., neoplasm, "cardiac asthma," etc.) is not due to any direct influence of the original causative lesion. These patients may possess in their bronchi what might be called an asthmogenic tendency, which lies dormant perhaps for years until activated by a lesion such as neoplasm, tuberculosis, cardiac disease, or pneumonoconiosis. These processes then act as triggers to set off the dormant asthmatic tendency. It seems difficult otherwise to explain why, of the many patients with pulmonary neoplasm or hypertensive coronary disease, relatively few have asthmatic wheezing as a prominent symptom or why, of the many miners with chronic bronchitis and emphysema, relatively few contract miners' asthma. The development of asthma in such patients must depend upon some factor other than the associated pulmonary or cardiac lesion. Recently, for example, I saw a mine inspector, aged 50, with asthma of three years' duration whose father had miners' asthma. X-ray examination showed some associated emphysema but little fibrosis. He has responded very well thus far to allergy treatment similar to that given younger asthmatics. Fortunately he did not have much exposure to coal dust; otherwise, he surely would have had miners' asthma as his father did. Tissue predisposition must be important in such patients, despite an apparently negative atopic family history.

Differential diagnosis is of primary importance in the geriatric asthmatic. Detailed history and thorough physical examination, especially of the lungs and cardiovascular system, are paramount. Competent x-ray examination of the entire chest cavity should be a routine procedure in all these patients and, whenever necessary, such special cardiologic examinations as electrocardiography, determination of circulation time, etc. These should make it possible to arrive at the proper diagnosis and to distinguish true allergic bronchial asthma from the nonallergic asthmas, including so-called asthmatic bronchitis and cardiac asthma. The diagnosis is established more definitely by the presence of increased numbers of eosinophils in the blood and the nasal and bronchial secretions; a history of associated allergic conditions such as allergic rhinitis, migraine, urticaria, etc. and specific positive skin reactions.

TREATMENT

When the diagnosis of allergic asthma has been made, the patient should be managed as though he were 20 or 30 instead of 50 or 60. Attempts should be made to determine the specific allergen or allergens by history, allergic tests, and clinical diet trial. It should be kept in mind that the skin of the geriatric is less reactive than that of younger persons and that positive reactions of even doubtful or slight degree should be considered important until proved otherwise. Diet trial should be carried out whenever food allergy is suspected. But it must be remembered that the nutritional state in the old as in the very young can be greatly impaired by severe or prolonged dietary restriction unless proper precautions are observed. Provision should be made for adequate caloric intake and for supplemental vitamins and minerals. Diet trial often will improve the condition of such patients, especially those previously thought to have "infectious" or "intrinsic" asthma.

As stated above, there is no proof that infection, especially in the paranasal sinuses, is the most important cause of asthma in the geriatric patient. Care is therefore needed in choosing treatment for these patients, even when there is x-ray evidence of sinus infection. I once had an elderly asthmatic patient who, though his condition was much improved with conservative allergy treatment, was discouraged by the persistence of mild attacks. A radical sinus operation was advised by his otolaryngologist, who had treated him for a long time for nasal difficulties. While I was not at all certain it was essential, I made no effort to interfere. The patient died from a complicating pneumonia a week after the operation. Since then, unusual caution has been exercised with these patients; furthermore, such procedures are seldom advocated except when purulent infection that does not respond to ordinary drainage and treatment exists. As nearly as can be judged from the reports in the literature,[14] as well as from subsequent clinical experience, the results of conservative treatment are just as good as, if not better than, those of radical sinus surgery. Conservatism in treatment is the keynote of success in all geriatric asthmatics.

The treatment of asthma in the aged is generally the same as in younger persons—elimination or avoidance of the offending allergens, or desensitization when the former is not possible. As in young children, due care should be exercised in administering extracts of dust, pollens, molds, or bacterial vaccines to avoid constitutional reactions, which may upset older patients more than younger persons. We sometimes see older asthmatics who previously received large doses of vaccines or dust extracts and who seem to get well even faster than younger and previously untreated asthmatics with only simple symptomatic treatment. The improvement in these patients probably is due largely to discontinuance of the injections of extracts in a dosage which did more harm than good. When in doubt, saline injections should be substituted for several weeks. If improvement follows, it is certain that the allergenic extract was causing reactions. The dosage then either is modified accordingly or the injections are discontinued entirely. Except for these precautions, the specific desensitization procedures are the same in the geriatric as in younger patients.

More care should be exercised, however, in the use of nonspecific methods of desensitization, especially in relation to fever therapy provoked by intravenous injections of typhoid or colon bacilli. The vascular systems of the aged naturally will not withstand the shock of sudden reactions as easily as those of younger persons; unless these injections are given cautiously, severe untoward or even fatal reactions may follow. When in doubt, it is best to avoid them.

Regardless of cause, drug therapy for symptomatic relief is an essential part of treatment in the geriatric asthmatic. As a rule, the same drugs are employed for any asthmatic patient, regardless of age. Of all drugs used, potassium iodide is one of the mainstays in treatment. Given in doses of 10 or more grains (0.60 Gm. or more) three times daily it seems to have a particularly beneficial effect on the elderly asthmatic. Whether this is due alone to its liquefying effect on the sputum or to some peculiar alterative effect on the tissues of the aged as well is not known; nevertheless, it is very helpful during the subacute or chronic stages. Ephedrine or one of its synthetic substitutes may be given at the same time, but more care should be exercised in their use, especially in the older male patient with prostatic hypertrophy. Ephedrine has produced in some patients such vesical tenesmus that prostatic surgery was considered; when the symptoms disappeared afte the medication was discontinued, the urologist realized that the symptoms were being provoked by the ephedrine and operation was avoided. Therefore, if the ephedrine drugs are to be used in older patients, smaller doses should be employed than in younger adults.

Treatment of the acute asthmatic attack in the aged generally is like that in any other asthmatic. Epinephrine by injection or aerosol still is the mainstay, with aminophylline by mouth, rectum, or intravenous injection as a substitute or supplement when epinephrine either is ineffectual or cannot be used. The question whether to use epinephrine or aminophylline for the relief of the acute attack often arises in the geriatric because of the likelihood of hypertension. If the hypertension is benign or essential, epinephrine in small doses can be used without fear to relieve acute asthma. Practitioners often are afraid to use it in such circumstances because they feel the epinephrine might increase the blood pressure. In my experience, however, it does the opposite. The relief of the asthma afforded by epinephrine usually reduces the blood pressure, which had been elevated by the vascular strain induced by acute asthma. One should not hesitate, therefore, to use small doses of epinephrine for relief of acute attacks unless the patient shows definite evidence of organic cardiac disease, especially involving the coronary artery. In those circumstances, the drug of choice should be aminophylline, given either orally or rectally, or, in acute attacks, by intravenous injection. In the latter instance, it should be administered slowly and cautiously. The fatal reactions after intravenous injections of aminophylline reported by Merrill[15] in 1943 occurred mostly in asthmatics with severe organic cardiovascular disease and might have been due either to rapid administration or to the fact that these patients were *in extremis*. In such instances, aminophylline rectally should be tried first and, if ineffective, may then be given intravenously in smaller dosage. This is also the only instance in which morphine may be given justifiably to an asthmatic patient. Since morphine depresses the respiratory system, its use in other asthmatics is contraindicated. But if a diagnosis of cardiac asthma has been established, it then can be given with benefit. If in doubt, meperidine (demerol®) hydrochloride may be somewhat safer, although it too should not be used unless essential. The aged, like children, do not tolerate sedatives such as barbiturates or morphine drugs as well as do younger persons; hence more care is needed in their administration.

Two other remedies sometimes given to the geriatric patient, whether asthmatic or not, are digitalis and alcohol. The indications for their use are not always clear, nor is there certanty as to their value. Unless cardiac insufficiency exists, the efficacy of digitalis is doubtful. Alcoholic drinks are believed to be tonic and supportive to the older person. Unless there is clinical evidence that their imbibition aggravates the asthma, they may be useful adjuncts. Relief of mild attacks might be obtained by their moderate use.

EMPHYSEMA

The most important complication of asthma in the geriatric is emphysema. This will be present in varying degrees depending upon the character and chronicity of the asthma. When asthma begins after 40 and recurs in the form of acute attacks, little emphysema probably will result. But if asthma becomes chronic and lasts for five years or more, emphysema of increasing severity will follow. It is especially troublesome in patients with asthmatic bronchitis in whom it is responsible for the annoying dyspnea accompanying the cough. Emphysema in these patients is due to more or less continuous overdistention of the pulmonary alveoli, leading to loss of elasticity of the connective tissue and its eventual destruction; it is much like an overstretched rubber band that fails to recoil. Increasing emphysema results in increasing reduction of pulmonary function, indicated by vital capacity or by bronchospirometric tests and clinically by increasing dyspnea. Little can be done to alter the status of a patient with permanent tissue changes indicated by a fixed chest wall. Nevertheless, some relief may be afforded by symptomatic measures to counteract the asthmatic wheezing, the cough, and the associated bronchial infection. In addition, some patients will derive benefit from the abdominal belt used in emphysema and perhaps from breathing exercises designed to improve diaphragmatic excursions or from a positive pressure-oxygen apparatus.

CONCLUSIONS

Asthma in geriatric patients usually has the same general characteristics, etiology, and clinical features as in younger people. However, the geriatric asthmatic differs in certain respects from the younger adult asthmatic, as does the asthmatic child. He also presents different diagnostic problems, especially those in connection with intrathoracic and cardiovascular conditions which require special attention and methods of diagnosis. Treatment, although generally the same in principle, also brings up special considerations and problems, as, for example, in the use of epinephrine, ephedrine, and aminophylline, which are of less moment in younger individuals. Conservatism *is the keynote to successful* treatment of the geriatric asthmatic. Properly utilized, these measures will enable the practitioner to attain the ideal goal of successful treatment in the geriatric patient, which should be to add life to his years as well as years to his life.

PHYSIOLOGICAL BASIS FOR PRESERVATION OF FECAL CONTINENCE AFTER RESECTION OF RECTUM

Eugene A. Gaston, M.D., Framingham, Mass.

Preservation of the anal sphincters in resection of the rectum can have but one aim, the retention of fecal continence. If this aim is to be realized, the mechanism by which fecal continence is normally maintained should be understood. The experimental work of McVay,[1] Gilchrist and David,[2] Glover and Waugh [3] and others [4] indicates that lymphatic metastasis from cancer of the rectum does not take place in a retrograde or distal direction until the proximal nodes lying in the mesosigmoid are largely blocked by malignant cells and the lymph stream thereby forced into collateral channels. On the basis of this work some surgeons have concluded that it is both safe and desirable to preserve the anal sphincters when resecting the rectum for malignancy. Other surgeons have violently disagreed with this view on the basis that the less radical, sphincter-preserving operation will result in fewer cures. The purpose of this paper is not to enter into a discussion of this controversial point but rather to summarize the physiological basis on which fecal continence is maintained. It seems obvious that if the anal sphincter is preserved, but its function lost, little or nothing has been accomplished.

TYPES OF FECAL CONTINENCE

Fecal continence may be defined as the ability to retain the contents of the colon until their expulsion is convenient. To understand how this is accomplished in normal persons, it is of the greatest importance to realize that fecal continence may be subdivided into reservoir continence (previously termed colonic continence) and sphincteric continence.

Reservoir Continence.—The left colon is fundamentally a reservoir organ and, like other smooth muscle reservoirs, automatically and without sensation adapts itself, up to a given point, to the bulk of its contents. When this bulk reaches a certain magnitude, peristalsis begins and the fecal mass is ejected. This ejection is beyond voluntary control. However, it is to be noted that feces are retained in the left colon for appreciable periods of time, 24 to 48 hr., and that freedom from colonic emptying over such periods constitutes a type of continence that has nothing to do with anal sphincters. Indeed, if the rectum and anal sphincters are entirely removed and a sigmoid colostomy established through the abdominal wall, this reservoir function of the colon can, by attention to diet and colonic irrigations at regular intervals, be utilized to produce a type of continence which experience has shown to be surprisingly satisfactory. For convenience, this has been termed reservoir continence, and it cannot be too strongly emphasized that it is retained whenever all or part of the left colon is preserved. Thus, if a sigmoid colostomy is established on the perineum and encircled by anal sphincters which

are entirely functionless, reservoir continence can be developed by the same measures used in abdominal colostomy and the resulting continence mistakenly attributed to the retained sphincters. There is reason to believe that, in a number of reported series in which the functional value of retained sphincters has been evaluated, exactly this mistake has been made.

Sphincteric Continence.—The term sphincteric continence refers to the active contraction of the striated muscle of the external anal sphincter, which thereby resists the propulsive force of colonic peristalsis. Denny-Brown and Robertson[5] have shown that there is no damping, or inhibitory, effect on colonic peristalsis when the sphincter is voluntarily contracted. The sphincter therefore acts by mechanically blocking the progress of the fecal mass, and the force of sphincteric contraction must exceed the propulsive force of colonic peristalsis to be effective.

It is worthy of emphasis that normal persons have both reservoir continence and sphincteric continence; that is, a smooth muscle reservoir lies above normally functioning sphincters. This is an important consideration when the ileum, which normally is not a reservoir organ, is brought down to the anal sphincters after total colectomy for such diseases as ulcerative colitis and multiple polyposis.

THE ANAL SPHINCTERS

Textbooks of anatomy commonly describe two anal sphincters: the internal and the external. The internal sphincter consists of a condensation of the circular smooth muscle fibers of the rectum. Like smooth muscle elsewhere in the body, it is under the control of the autonomic nervous system and, as will be demonstrated, takes part merely in the peristaltic activity of the smooth muscle of the rest of the rectum and has nothing to do with sphincteric continence. Thus, the statement, repeatedly noted in surgical literature, that division of the internal sphincter causes incontinence is misleading. Surgical division of the internal sphincter is necessarily accompanied by complete division of the external sphincter, and it is this latter maneuver which results in loss of sphincteric continence.

The external anal sphincter consists of striated muscle, is innervated by somatic nerves, and, therefore, is under the control of the voluntary nervous system. It is commonly assumed that this sphincter functions as a simple purse string. That such is not the case has been demonstrated by experimental studies which have been previously reported.[6] These studies point the way to successful methods for the preservation of fecal continence and have been amply confirmed by clinical observation.

SUMMARY OF EXPERIMENTAL STUDIES

Like striated muscle in other parts of the body, the external anal sphincter fatigues quickly. This fact can be readily confirmed by introspection and has been demonstrated experimentally by placing a balloon, connected for kymographic recording, within the anal canal. After the temporary spasm caused by the introduction of the balloon has subsided and the basic tonus of the sphincter has been noted, the subject is requested to contract the sphincter with all possible force and for as long a time as possible. An analysis of graphs obtained by this method indicates that maximal contraction is sustained for only a few seconds and, even with continued effort, is followed by a steady and progressive fall of sphincter tone until the base line is reached. In a series of normal persons, the average maximal contraction was 44 cm. of water and the average length of time during which any contraction was possible was 53 sec.

The fact that the sphincter fatigues so readily makes it evident that some mechanism is required to correlate the activity of the sphincter with the peristaltic activity of the colon. The fact that such a correlation exists has been demonstrated by filling the colon to the limit of toleration with saline solution by means of an enema. This stimulates peristalsis, and the increases in intrarectal pressure brought on by peristalic waves have been recorded kymographically. Balloon recordings of sphincter tone made simultaneously demonstrate that with each peristaltic wave the increased pressure exerted against the outlet is countered by an appropriate degree of contraction of the anal sphincter. As the peristaltic wave recedes and the pressure against the sphincter falls, relaxation of the sphincter takes place, only sufficient tone being maintained at any given moment to counter effectively the peristaltic thrust. Since peristaltic waves ordinarily last less than one minute and since the peak of each wave lasts only a few seconds, it is evident that maximal contraction of the sphincter is required for only a few seconds at a time and that its endurance is sufficient for the demands ordinarily put upon it.

The following facts were repeatedly and consistently demonstrated in normal adults by the application of a method which made it possible to record simultaneously and independently on a kymograph the tone of each of the two sphincters:

1. Stimulation of the rectum by distending a balloon within its lumen caused a sustained fall of internal sphincter tone. This fall was proportional to the degree of distention of the rectal balloon and was sustained until the balloon was deflated. Thus, the internal sphincter evidently plays no part in sphincteric continence but rather, by its relaxation during rectal stimulation, prepares the way for defecation. This rectal stimulation also caused a sharp rise of external sphincter tone which was of short duration. The greater the stimulus applied to the rectum (i. e., the larger the balloon) the greater was the force of the corresponding contraction, but the duration of the contraction was not increased. Thus, as the intrarectal pressure was increased by enlargement of the balloon, the external sphincter contracted only sufficiently to maintain continence. As soon as the intrarectal pressure was diminished by relaxation of the smooth muscle of the rectum, sphincteric contraction was no longer needed and fell rapidly to its original level.

2. Stimulation of the sigmoid colon by the same method caused no change in the tone of either the internal or the external sphincter.

3. When the balloon was placed high in the rectum, near the rectosigmoid junction, the stimulus resulting from its distension caused the characteristic responses of both the internal and external sphincters; but the responses were feeble. When a similar stimulus was applied to the midrectum, the magnitude of the responses was greater. When the stimulus was applied to the distal portion of the rectum, still greater sphincter responses

[6] Gaston, E. A.: Surg., Gynec. & Obst. 87: 280-290 and 669-678, 1948.

were obtained. Thus, the farther distally in the rectum the stimulus was applied, the greater were the sphincter responses.

4. Stimulation of the rectum in a patient with complete transection of the spinal cord produced a normal relaxation response of the internal sphincter but no corresponding contraction response of the external sphincter.

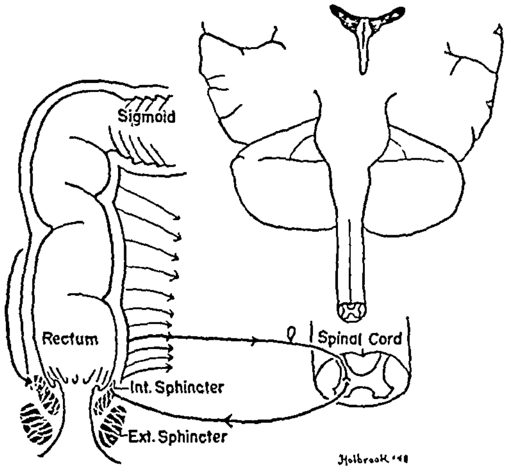

Fig. 1.—The reflex connections between the rectum and the internal sphincter.

COMMENT

The experimental findings indicate that nervous reflexes exist between the rectum and the internal sphincter and between the rectum and the external sphincter and that there is no such reflex connection between the sigmoid colon and the sphincters. The receptor units which initiate these reflexes are sparse per unit area in the upper rectum and become progressively more numerous per unit area in the lower rectum. Because the internal sphincter reflex is retained in complete transection of the spinal cord, it is evident that higher cerebral centers are not necessary to its characteristic relaxation response (fig. 1). This point is of only academic interest since, as has been shown, the internal sphincter plays no part in sphincteric continence. However, the external sphincter reflex is destroyed when the spinal cord has been transected; and cerebral connections must, therefore, be required for its completion (fig. 2). The reflex arc of the external sphincter may also be broken by division of the peripheral motor nerves which supply the external sphincter. It is conceivable that such an accident could occur during resections of the rectum since the inferior hemorrhoidal nerves to the external sphincter are closely applied to the inferior surfaces of the levator ani muscles, which must be divided when the lower part of the rectum is freed.

Most pertinent to this discussion, however, is the fact that the reflex arc can be broken by removal of the afferent nerves which originate only in the rectum. When all of the rectum is removed, the receptor units of the rectosphincteric reflexes are also removed, and the mechanism by which the external sphincter is warned as to when and to what extent its services are required is destroyed. It is therefore evident that the rectum is as essential to sphincteric continence as is the sphincter itself.

It has been possible to confirm the importance of the afferent portion of the reflex arc by investigation of a woman patient who had the entire rectum removed and the sigmoid colon pulled down to take its place. The external sphincter and its motor nerve supply were preserved intact, for it can be voluntarily contracted and has normal strength and a normal fatigue curve. Sphincteric continence does not exist, however, because bowel content escapes before there is any warning that its escape is imminent, and balloon studies show no reflex response of the sphincter when the "new rectum" is stimulated. It has been necessary to place this patient on a colostomy regimen consisting of attention to diet and colonic irrigations every second day. On this regimen reservoir continence, exactly as in a patient with abdominal colostomy, has been developed to the point where she is able to carry on her usual activities. From the standpoint of fecal continence, the retained sphincter is of no functional value.

Since resection of all of the rectum leads to loss of sphincteric continence, the question arises as to how much rectum must be retained in order to preserve satisfactory sphincteric function. From the study of a number of patients in whom varying amounts of rectum have been preserved it would appear that approximately the distal fourth of the rectum is required for this purpose. In this respect it should be emphasized that the rectum varies in length in different persons. It is longer in women than in men and longer in tall people than in short people. For this reason it is probably best to express the amount of rectum that is required for the preservation of sphincteric continence in terms of the initial length of the rectum, as measured with the sigmoidoscope

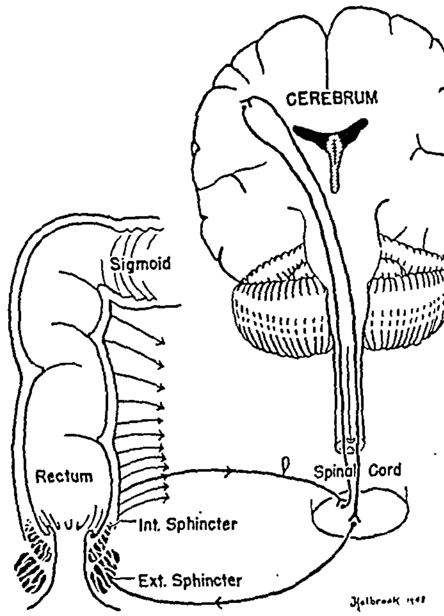

Fig. 2.—The reflex connections between the rectum and the external sphincter. Cerebral connections are required for the completion of this reflex.

Because the sensory nerve supply of the distal colon and rectum parallels that already described for the afferent portion of the rectosphincteric reflex arc, it is possible to determine clinically when the reflex is intact. If a balloon is distended in the sigmoid colon, sensation is produced in the lower abdomen, usually in the midline but often in the left lower quadrant, which is interpreted as a cramp and not as a desire to defecate. When the balloon is pulled down to a level just below the rectosigmoid junction, a similar degree of distension causes in the sacral or perineal region a sensation which is interpreted as a mild desire to defecate. The lower in the rectum the balloon is placed, the greater is the sacral or perineal sensation resulting from an equal degree of distension. Therefore, if the patient who has had a portion of the rectum removed has a sensation located in or near the perineum which approximates that to which he is normally accustomed when a bowel movement is imminent, and if he is able to contract voluntarily the external sphincter in a normal fashion, both the afferent and efferent portions of the reflex are intact, and true sphincteric continence exists.

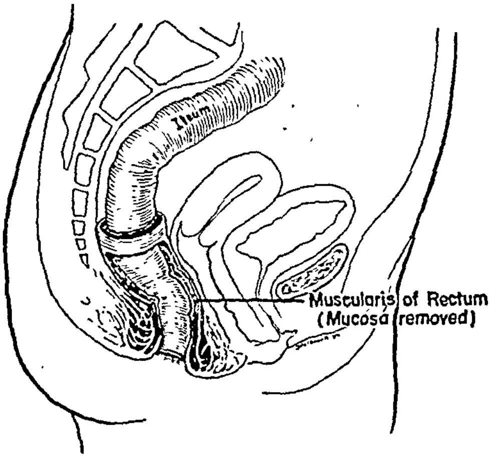

Fig. 3.—Diagram of Ravitch operation. Since the muscular wall of the rectum is retained, the afferent portion of the rectosphincteric reflex is preserved.

Since reservoir continence alone can be developed to such an extent that an individual is able to resume his social obligations without embarrassment, it has been of some interest to observe a patient who has only sphincteric continence. This concerns a woman, aged 43, who suffered recurrent bouts of ulcerative colitis for a period of 11 years. A terminal ileostomy was done in June, 1947, because of a severe exacerbation of the disease, and was followed by dramatic improvement in her general condition. On March 4, 1949, approximately two years later, a total colectomy and anal ileostomy were performed using the technique described by Ravitch.[7] The entire colon and all but the distal 7 cm. of the rectum were removed. The mucosa was removed from the retained distal segment of rectum and the terminal ileum brought through this muscular cuff and sutured in place (fig. 3). Thus, the sphincter and its motor nerve supply were not disturbed and the afferent portion of the rectosphincteric reflex arc was preserved in the retained muscularis of the rectum. The postoperative convalescence was complicated by pelvic sepsis, which required the reestablishment of an abdominal ileostomy and local drainage. Eventually the sepsis cleared and healing was complete. The abdominal ileostomy was closed in November, 1949. Approximately five months later the patient had a perfectly normal anal sphincter and sufficient rectal muscularis with its afferent nerve supply so that a normal rectosphincteric reflex remained. The desire to defecate was manifested by a normal sensation located in the perineum. While she was able to retain the contents of the ileum by sphincteric contraction in a normal fashion, she was able to do so for only short periods of time and went to stool at least once an hour throughout the day and night. It seems evident that the poor result in this case is due to the fact the terminal ileum is not normally a reservoir organ and, until that time, had failed to take over the function of a reservoir. Thus, sphincteric continence exists without associated reservoir continence and the functional result is much less satisfactory than when the reverse is true.[8]

SUMMARY AND CONCLUSIONS

Fecal continence can be subdivided into reservoir continence and sphincteric continence. Both reservoir continence and sphincteric continence must be retained if normal fecal control is to be preserved. Reservoir continence alone is of greater practical value than sphincteric continence alone.

The preservation of reservoir continence requires the retention of some portion of the left colon to act as a reservoir organ. The ileum is often unsatisfactory for this purpose.

Sphincteric continence depends upon a nervous reflex, the afferent fibers of which arise in the rectum, the efferent fibers terminating in the external anal sphincter. The rectum is therefore as much a part of the sphincter mechanism as is the sphincter itself. If all of the rectum is removed, sphincteric continence is lost because this reflex arc is broken by removal of the afferent nerves.

If sphincteric continence is to be preserved in rectal resections, it is necessary to retain not only the external anal sphincter but also some portion of the immediately superjacent rectum. Probably the distal fourth of the rectum is sufficient for this purpose.

[7] Ravitch, M. M.: Surgery 24: 170-179, 1948.

[8] Apparently the ileum is sometimes able to take over the function of a reservoir, for Ravitch has reported good functional results in several of his cases. However, a number of other surgeons have found the operation unsatisfactory because of the intolerable frequency of stools.

The Cortical Steroids.—The measurement of 17-ketosteroids in the urine is of no value in assessing the rate of secretion of cortical hormone in man. Considerable confusion has arisen in the clinical literature due to misinterpretation of the significance of urinary 17-ketosteroids. There is a distinct difference between the pattern of urinary steroids in hypercorticism induced by ACTH administration and in adrenal hyperactivity induced by stress. In hypercorticism both corticoids and 17-ketosteroids are excreted at a rate greater than normal; in adrenal hyperactivity associated with stress the corticoids are increased but the 17-ketosteroids are usually decreased. The evidence indicates that the metabolic pathways concerned with the "utilization" and/or degradation of the cortical steroids undergo qualitative and possibly quantitative changes under the influence of stress.—George Sayers, Regulation of the Secretory Activity of the Adrenal Cortex, *The American Journal of Medicine*, May, 1951.

NONSPECIFIC ULCER OF THE SMALL INTESTINE

REPORT OF FIVE CASES

Patrick C. Shea Jr., M.D., Atlanta

Nonspecific ulcer of the small intestine is one of the rare and particularly enigmatic diseases of the abdomen. Little is known of this intestinal lesion. The clinical picture is vague and confusing, making preoperative diagnosis almost an impossibility. The etiology is unknown. The histologic characteristics are a matter of record, but they give little indication of the pathogenesis of the lesion.

Excellent papers have appeared in the literature tabulating the cases which have been reported and summarizing what is known of the disease.[1] This type of ulcer was first described in 1805 by Matthew Baillie; yet in 1947, when Evert, Black, and Dockerty [1a] at the Mayo Clinic made a study of the literature, they found a total of only 130 cases, including 14 from their own clinic. The purpose of this paper is to report five cases which were seen in the past three years in a city hospital which admits a yearly average of 22,000 patients.

REPORT OF CASES

Case 1.—W. D., a Negro man aged 39, had had persistent abdominal distention for 12 days, accompanied with intermittent colicky abdominal pain, nausea, and vomiting. The patient was acutely ill and had a temperature of 100.2 F. on admission. The abdomen was protuberant and hyperresonant to percussion. There was generalized tenderness referred to the right lower quadrant. Peristalsis was present but hypoactive. Examination of the rectum revealed moderate tenderness high on the right. Roentgenographic examination of the abdomen revealed severe distention of the entire small intestine.

Laparotomy was performed, and about 500 cc. of pinkish-tan peritoneal fluid was encountered. The distal ileum and the cecum were collapsed. The proximal small intestine was distended with fluid. In the midileum an area approximately 30 cm. in length was violaceous in color; multiple perforations were present and were loosely sealed with overlapped segments of dilated intestine. The intestine was emptied of its contents by aspiration through one of the perforations. The diseased segment was resected and an end-to-end anastomosis was established.

Postoperative examination of the small intestine by contrast roentgenogram, typhoid and brucellosis agglutination tests, and cultures of the urine and stool for typhoid bacilli were all negative. The patient was seen three months later and was found to be asymptomatic.

Histologic Examination.—Near one end of the segment of ileum, there was a rent about 5 cm. in length that extended completely through the intestinal wall and had rather smooth edges. The serosal surface was shiny and mottled deep purplish-red. The intestine was edematous as was the mesentery attached to it. All layers of the intestinal wall were involved in a chronic inflammatory reaction. There were multiple areas of dissolution of the mucosa with ulceration, and healed lesions were present. The medium-sized veins and a few arteries in the wall showed segmental destruction of the vessel wall, associated with a developing thrombosis.

Case 2.—G. B., a Negro man aged 48, was admitted to the hospital for regulation of mild cardiac decompensation. There were no abdominal complaints, and the history concerning gastrointestinal disease was insignificant. On the fourth day mild pain developed in the left lower quadrant, accompanied with nausea. The pain persisted during the ensuing 24 hours and became increasingly severe and colicky.

The white blood cell count had risen from 6,700 on admission to 13,600; the nonprotein nitrogen blood level was 61 mg. per 100 cc. Blood pressure was 190 systolic and 140 diastolic; temperature was 101.8 F. The heart was well compensated but fibrillating slowly.

Examination of the abdomen revealed generalized tenderness referred to the left lower quadrant. Peristalsis was present but hypoactive. The liver was enlarged but nontender. Examination of the rectum was noncontributory.

Laparotomy was performed. There was no visible free fluid when the peritoneal cavity was opened. An area of thickened, edematous jejunum was noted approximately 45 cm. from the ligament of Treitz. In the middle of this area there was a patch 2.5 by 1 cm. in which the serosa was yellow and mottled with red. Palpation at that point demonstrated thinning of the intestinal wall. The entire thickened area, including margins of 5 cm. of normal intestine, was resected, and an end-to-end anastomosis was established.

The patient was examined two and one-half months after the operation and was found to be asymptomatic.

Histologic Examination.—The specimen was a segment of jejunum measuring 17 cm. in length. The mucosal surface was interrupted by a 3 by 1.5 cm. yellowish-green area of ulceration. The mucosa surrounding this area was fiery red. An ulcer involved a portion of the muscularis, the submucosa, and the mucosa. An acute inflammatory process extended through the wall of the intestine. The vessels appeared dilated and congested; several contained fibrin thrombi, and some of the vessel walls showed infiltration by polymorphonucelar leukocytes. The serosal surface showed acute inflammation and the presence of fibrin.

Case 3.—C. B., a boy aged 19, had had sudden onset of lower abdominal pain, colicky in nature and accompanied with one episode of vomiting, about six hours previous to admission. Several months previously an appendectomy had been performed for a ruptured appendix, later followed by division of adhesions to relieve intestinal obstruction. There had been no other complaints.

The patient's temperature was 100.2 F. on admission. There was moderate rigidity of the abdomen with extreme rebound tenderness over the umbilicus and in both lower quadrants. Peristalsis was absent. Examination of the rectum revealed tenderness high on the right and in the midline. Roentgenographic examination of the abdomen disclosed nothing of significance.

Laparotomy was performed by Dr. Lewis Sharman. There was a small amount of cloudy peritoneal fluid. Two perforations were noted approximately 25 cm. proximal to the ileocecal valve: One was approximately 1 cm. in diameter; the other, 3 mm. In the area of the perforations, the intestine was edematous and thickened; distally, the lumen was narrowed but not occluded. There was no evidence of mechanical obstruction. The involved area of the ileum was resected, and an end-to-end anastomosis established.

Contrast roentgenographic examination of the abdomen one month after the operation revealed a normal ileum. The patient was seen at intervals for three years; the only complaint he had was occasional cramping abdominal pain. Results of roentgenographic examination of the gastrointestinal tract and physical examination at his last visit were normal.

Histologic Examination.—The specimen was 5.5 cm. of ileum, measuring in circumference 7.5 cm. at one end, 3 cm. in the middle, and 4.5 cm. at the distal end. Just proximal to the constricted area was a perforation 1.5 cm. in diameter with ragged edges. The surrounding serosal surface was granular and cov-

J.: Spontaneous Perforation of Primary Jejunal Ulcers, Irish J. M. Sc. (sér. 6) 198, 1931. (*c*) Ebeling, W. W.: Primary Jejunal Ulcer, Ann. Surg. **97:** 857, 1933.

ered by an exudate composed of fibrin and neutrophils. The mucosal surface showed regenerating epithelium with hyperplasia, but there was no evidence of malignancy. The muscular layer terminated a short distance from the perforation by gradually thinning. The appearance of the muscular coat suggested that the perforation occurred at the site of a diverticulum.

Case 4.—M. D., a man aged 80, had a history of indigestion for five days prior to admission. He denied previous intestinal disorders. A local physician reported that two days before admission, examination had revealed a hernia which was easily reducible; the abdomen had been soft and nontender, and peristalsis had been active.

Examination on admission revealed an acutely ill patient with a temperature of 102 F. The odor of his breath was slightly uremic. Rales were present in both lung bases. The abdomen was slightly distended and exquisitely tender, with rebound tenderness in the entire lower abdomen. Peristalsis was absent. There was a cystic, nontender mass in the left inguinal region. Examination of the rectum revealed nothing significant. A roentgenogram of the abdomen disclosed no abnormality and a chest film revealed no evidence of pulmonary disease. The white blood cell count was 13,500; the nonprotein nitrogen level was 50 mg. per 100 cc.

Herniotomy was performed, but no incarcerated intestine was found. Therefore, an exploratory laparotomy was performed by Dr. Wilbur Scott. In the proximal 30 cm. of the jejunum there were matted and adherent intestinal loops bound one to another with fine fibrinous and fibrous adhesions; in the midportion of this area was a hemorrhagic, friable segment of intestine 15 cm. in length, in the center of which a perforated ulcer was present. Biopsy was performed, and layer transverse closure of the intestine was used.

Summary of Five Cases of Nonspecific Ulcer of the Small Intestine

Case	Age, Yr.	Sex	Race	Preoperative Diagnosis	Duration of Symptoms	Location of Ulcer	Complications	Operative Treatment	Result
1	39	M	Negro	Ruptured appendix with intestinal obstruction	12 days	Ileum	Perforation	Resection, end-to-end anastomosis	Recovery
2	48	M	Negro	Mesenteric thrombosis or diverticulitis of sigmoid	1 day	Jejunum	....	Resection, end-to-end anastomosis	Recovery
3	19	M	White	Inflammation appendiceal stump or intestinal obstruction	6 hr.	Ileum	Perforation	Resection, end-to-end anastomosis	Recovery
4	80	M	White	Strangulated hernia	5 days	Jejunum	Perforation	Transverse closure	Died after 5 days
5	34	F	Negro	Jejunitis with ulcer (X-ray) or intestinal obstruction	8 yr.	Jejunum	....	Resection, jejunoduodenostomy	Recovery

Postoperatively the patient was moderately disoriented for 48 hours and then gradually improved. On the fifth day his temperature suddenly rose to 106 F.; he died the following day. Death appeared to result from massive pulmonary embolism. Permission for necropsy was not granted.

Histologic Examination.—Biopsy of the jejunum showed the mucosa to be absent in some sections with blood clot protruding through the space. The clot contained acute inflammatory cells out of proportion to the red cells. The inflammation extended throughout the submucosa at the border. There was early degeneration of the muscle and connective tissue fiber.

Case 5.—L. O., a Negro woman aged 34, had been observed in 1941, at which time she had a history of hematemesis and melena. An ulcer niche in the pyloric region was seen on roentgenographic examination. There was no history of ulcer symptoms. She was readmitted in 1944 with a history of persistent nausea and vomiting and a weight loss of 30 lbs. (13.6 Kg.). Contrast roentgenographic examination of the gastrointestinal tract showed no abnormalities. In 1945, a moderate dilatation of the duodenal bulb and the proximal half of the duodenum was observed by roentgenogram. At that time there was a recurrence of postprandial nausea and vomiting, but the patient refused surgery.

In 1948, the patient returned complaining of a recurrence of melena, accompanied with cramping, gnawing epigastric pain, and persistent postprandial nausea and vomiting. Physical examination was noncontributory. Roentgenographic examination of the gastrointestinal tract revealed a constriction of the proximal jejunum; there was some dilatation proximal to the constricted area indicating a partial occlusion of the lumen of the intestine. A diagnosis of jejunitis with ulcer or high intestinal obstruction was made. The patient again deferred surgery.

The symptoms of upper intestinal obstruction persisted, and in 1949 laparotomy was performed by Dr. John Durden. The distal duodenum and proximal jejunum were markedly dilated, and the wall of these areas was slightly thickened. Immediately distal to the dilated area was a narrowed area 2.5 cm. in diameter, and at this point an ulcer was found. Distal to the narrowed area the jejunum was normal. The upper jejunum was resected and an end-to-end jejunoduodenostomy established.

The patient's postoperative period was uncomplicated. At the end of six months she was asymptomatic and had gained weight.

Histologic Examination.—The specimen was a segment of the distal duodenum and proximal jejunum measuring 24.5 cm. in length. The proximal end measured 7.5 cm. in diameter and had a slightly thickened wall. The dilated portion ended abruptly 3.5 cm. from the proximal end of the specimen, at which point there was a puckered stricture with the diameter narrowed to 2.5 cm. The wall here was slightly thickened and indurated. There was a shallow ulceration with a pinkish-tan granular base and sloping edges. In the adjacent mesenteric fat 16 lymph nodes varying from 2 to 15 mm. in diameter were identified. There was evidence of minimal regenerative activity of the mucosa at the edge of the ulcer, as evidenced by a single layer of flattened epithelial cells extending over the granulation tissue for a short distance from the edge of the mucosa.

COMMENT

The diagnosis of nonspecific ulcer of the small intestine is very difficult. A case reported by Ebeling[1c] in 1933 was the first in which diagnosis was made preoperatively. In the chronic type the lesions form slowly, and months or years of vague and bizarre, but definite, abdominal discomfort, and occasionally even hemorrhage into the intestinal tract, may be suffered by the patient. On the other hand, perforation of the intestine may actually occur without previous indication of pathologic change, the first symptoms being those of perforation of a hollow viscus into the peritoneal cavity. These symptoms may simulate various acute abdominal conditions, such as ruptured peptic or duodenal ulcer or acute appendicitis.

In four of the five cases presented here the condition was acute, with perforation in three. The duration of symptoms ranged from 12 days to six hours. The chief symptoms were nausea, vomiting, and nonlocalized, persistent abdominal pain which had started suddenly and was occasionally colicky. Neither melena nor hematemesis was present. The patients had fever on admission, usually leukocytosis, abdominal distention with tenderness, rebound tenderness, and rectal tenderness. Roentgenographic studies of the abdomen were without diagnostic significance.

In the chronic case there was a history of melena and considerable weight loss. The patient was observed over a period of approximately nine years. In the eighth year the roentgenographic studies of the gastrointestinal tract indicated a contracted area of jejunum with dilatation behind that area. A tentative diagnosis of jejunal ulcer was made. This was the only instance in the five cases reported here in which the correct diagnosis was made preoperatively. It is obvious that the symptoms in the acute cases were of little value for a specific diagnosis. Even those in the chronic case made diagnosis problematic.

As reported by others, the majority of these cases occurred in adult males.

The mortality rate from this lesion is high. Morrin[1b] reported a collection of 85 cases with 56 fatalities, or a mortality rate of 66 per cent. In the 45 cases collected by Evert and his associates[1a] following Morrin's report, there were 21 deaths, a mortality rate of 47 per cent.

Surgery is the only means by which this lesion has been successfully treated, but there is no single procedure used for its successful removal. Although the reports in the literature indicate that simple closure may reduce the risk of operation, it was the general opinion that resection would be the better procedure.

Free perforation was present in 26 of the 45 cases collected by Evert and associates. Simple closure was used in nine, with one fatality; excision of the ulcer and transverse closure in three, with one fatality; and resection and anastomosis in five, with three fatalities. In Morrin's collection there were 38 cases with perforation in which some type of operative procedure was used: suture alone in 23, with 10 fatalities; and resection in six, with two fatalities. Robinson and Wise,[2] reviewing 39 cases in 1940, found that 18 were treated by resection and anastomosis, with four fatalities, and 15 were treated by simple transverse closure, with six fatalities.

Resection and establishment of an end-to-end anastomosis was carried out in four of the five cases reported here; in two of these, perforation had occurred. There was perforation in one (case 4) in which transverse closure was used. This was the only case which terminated in death, although death appeared to result from pulmonary embolism. These five cases do not warrant definite conclusions, but the impression from them is that resection would be the procedure of choice even in patients who were poor risks for any surgery.

The patients whose cases are discussed here were prepared for operation by the routine used in this hospital for intestinal surgery, whether emergency or elective. Levin intubation with Wangensteen suction was performed, and blood and fluids were administered intravenously as indicated, depending upon the state of dehydration. The preferred anesthesia was spinal with thiopental analgesia, but gas-oxygen-ether closed inhalation was used if spinal anesthesia was contraindicated.

The patient usually is in no condition to withstand an extensive or prolonged search at laparotomy for the pathologic area, yet it is essential that the small intestine be carefully examined for these lesions when no other pathology which would account for the symptoms is found. If the possible presence of this lesion is kept in mind, the search for the affected part may be more successful.

SUMMARY

Five cases of nonspecific ulcer of the small intestine are presented. Four of the cases were acute and diagnosis was not made until laparotomy was performed. One of the cases was chronic, and diagnosis by roentgenography was made preoperatively. Resection and establishment of an end-to-end anastomosis was carried out in four cases, in all of which the patients survived. One case, in which transverse closure was performed, terminated in death.

IMMUNITY IN TUBERCULOSIS

J. Arthur Myers, M.D., Minneapolis

Dependable immunity is established against smallpox by vaccination—why not against tuberculosis? This is the question Koch asked in 1882, and it is still being asked in 1950. Literally scores of physicians and scientists have diligently sought the answer. No pathogenic micro-organism has deceived the medical profession with respect to immunity as often, as continuously or as completely as the tubercle bacillus.

HISTORICAL AND EXPERIMENTAL BACKGROUND

In 1920 and 1921 I was assigned to projects that offered unlimited opportunities to study tuberculosis in all of its stages of development. One of them was concerned with aiding in the organization and direction of a tuberculosis control program among students of the University of Minnesota; the other, with a tuberculosis control program for all school children of Minneapolis. I also participated in other projects that included persons beyond university age and even through the period of senility.

The literature revealed numerous attempts to immunize artificially against this disease. So-called immunizing agents had been produced from bacilli killed by various methods such as heat, light rays and lipid solvents. Some workers reported apparent success, but ultimately all failed.

The attempt to vaccinate with living virulent and attenuated tubercle bacilli was begun by Cavagnis in 1886. Before the nineteenth century closed, several others were active in this field. In 1902 von Behring administered intravenously to calves living human type tubercle bacilli with greatly reduced virulence for guinea pigs. Inoculation with this bovovaccine appeared to re-

First Hyman I. Spector Lecture, presented at St. Louis University School of Medicine, St. Louis, April 12, 1950.

sult in definite resistance to virulent tubercle bacilli. It was recommended for and used in large numbers of cattle in several nations, and its use was made obligatory in some European provinces. Von Behring's claims were so convincing that the German government constructed a large institute where he made the vaccine for worldwide distribution. The passage of time proved that the apparent resistance produced by this vaccine was of short duration and not sufficiently effective to be of practical value. Numerous investigators entered the field, including Koch, Neufeld, Miessner, Heymans, Klimmer, Arloing and Theobald Smith, seeking to modify von Behring's method so as to make it effective.

Calmette and Guérin, working with virulent bovine bacilli which Nocard had isolated from the udder of a tuberculous cow (1902), observed that the bacilli grew perfectly on a special medium. Moreover, their virulence diminished progressively until large doses did not seem to harm calves for at least 18 months. These calves also manifested apparent resistance to virulent tubercle bacilli. In 1921 Calmette named this organism BCG (bacillus Calmette-Guérin) and in 1924 declared it a *virus fixé*.

When our work began, in 1920, all the previous experiments aimed at production of dependable artificial immunity had failed. Although sweeping claims were being made for the widely discussed efficaciousness of BCG, its use was still limited to animals. We decided to support a fundamental program in which tuberculosis is treated as a contagious disease and by which tubercle bacilli are prevented from invading living human and animal tissues. Our predecessors and colleagues had completed a sanatorium building program in 1918, but there were still many persons with contagious tuberculosis unaccommodated in sanatoriums. Veterinarians were attacking the bovine type of tubercle bacillus, but there was still much contagious tuberculosis among cattle. Sanatorium staffs, public health workers, physicians in practice, nurses, social workers, veterinarians and a large segment of the citizenry of the state engaged in this fundamental tuberculosis control program.

EARLY CLINICAL TRIALS

By 1922 Weill-Halle of France was administering BCG to infants. Over the next few years the claims of Calmette and his disciples were so sweeping that we were faced with heavy pressure to infect those for whom we were responsible with this living tubercle bacillus in the hope of immunizing them. The opportunity to confer personally with Calmette as well as to hear him read a manuscript on vaccination of newborn infants came in 1926. He stoutly maintained that vaccination with BCG was harmless, that the virulence of the organisms was absolutely and permanently fixed and that efficaciousness in safeguarding infants from immediate environmental contagion had been "demonstrated beyond doubt." In our opinion Calmette had added nothing new, and his claims with reference to harmlessness and efficaciousness were not unlike those of many others who had preceded him but were later proved to be wrong.

As our tuberculosis control projects by fundamental methods progressed, we kept in close touch with reports of those attempting to immunize with BCG and later with vole tubercle bacillus. Calmette believed his vaccine to be so efficacious that when leading clinicians of France urged a carefully controlled study he refused them and encouraged mass vaccination without the benefit of scientific proof. Thus, scientists and outstanding physicians lost confidence in him. His reports of 1927 and 1928 were severely criticized by statisticians such as Greenwood and others, including the editor of the *British Medical Journal*. About the same time, Petroff stated that BCG had regained virulence in his laboratory. Then came the Lübeck disaster, in which 77 of 250 vaccinated infants died of tuberculosis (presumably from contamination of the vaccine).

Calmette's original work was on animals, particularly cattle (1908 to 1922), and he reported such good results that enthusiasm ran high. In the United States, veterinarians and others put BCG to the most rigid and carefully controlled tests, but they found it of no practical value. In fact, when subjected to the same exposure, cattle that had received BCG contracted as much destructive tuberculosis as the controls. The veterinarians of North America then proceeded with their long since established fundamental tuberculosis control measures. By such means they accomplished results that have never been attained anywhere in the world through the use of BCG.

After these catastrophes and other setbacks, enthusiasm for BCG reached a low ebb throughout the world except in Scandinavia, where Heimbeck (1927) and, later, others, including Holm and Wallgren, maintained interest. In the United States, Park and associates, of the New York City Department of Health, instituted a study on BCG among children in 1926. Rosenthal of Chicago brought BCG from France in 1934 and is now its most enthusiastic proponent in this country.

ACCUMULATION OF CLINICAL DATA

Soon after 1920 we observed that when children first became reactors to tuberculin a small percentage of them had fever, erythema nodosum, pleurisy, enlargement of hilar structures and small infiltrates in the lungs. When these manifestations subsided, the children appeared well. An occasional child had fatal pneumonia, meningitis or miliary disease. As the years passed, we observed many persons, particularly students of nursing and medicine, who first became infected with tubercle bacilli in adulthood. These adults responded exactly as children do when first infected, and the manifestations, such as erythema nodosum, pleurisy, enlarged hilar structures and the like, were essentially the same as those observed among children.

It is around these "allergic manifestations" that occur about the time hypersensitivity is first in evidence and for a short time thereafter that the BCG program has been developed for which so much enthusiasm has been manifested. A sizable number of workers have reported definitely less erythema nodosum, enlarged hilar shadows and other symptoms among children and young adults who have received BCG than among controls. Probably one reason for this observation is that after primary lesions were produced in the skin and regional lymph nodes with BCG, one would not expect as much evidence of such lesions in the lungs with markedly enlarged hilar lymph nodes. It would also seem likely that the allergy produced by an organism of low virulence like BCG would be of less degree than that from virulent tubercle bacilli; hence, less erythema nodosum.

Another reason is the comparison of unlike conditions. It has been contended that far more tuberculosis develops among students of nursing and medicine who become infected while in school than among those who enter with infections established. The fact is overlooked that those who enter as tuberculin reactors already have tuberculous lesions containing tubercle bacilli. When they became infected earlier in life, some of them, and others in the group from which they were drawn, had such manifestations as erythema nodosum, pleurisy, enlargement of hilar shadows and primary infiltrates. An occasional one had acute fatal tuberculosis and therefore was eliminated from the group. On entrance to professional schools, a few had evidence of calcific deposits or diaphragmatic changes. The majority had no abnormal x-ray findings, but the tuberculin reaction attested the presence of lesions. The above allergic manifestations developed in those who first became infected in school, but after these manifestations subsided their tuberculosis status was the same as that of their tuberculin reactor classmates on admission—that is, both groups then had primary tuberculous lesions containing living tubercle bacilli.

Among the subjects of some of our earlier observations were 160 medical students who entered as tuberculin reactors, and in 3.1 per cent of whom reinfection type of lesions developed while they were in school or soon after graduation; whereas, among 145 who became reactors while in school, demonstrable lesions developed in 9.6 per cent. This might be interpreted to mean that more than three times as many students who became reactors while in school acquired clinical tuberculosis than did those who entered as reactors. Actually this is not true. In fact, of the 9.6 per cent in whom demonstrable lesions were seen, primary complexes and pleurisy accounted for 6.2 per cent, whereas only 3.4 per cent acquired chronic reinfection type of tuberculosis. Thus, only the 3.4 per cent is comparable with the 3.1 per cent of clinical lesions among the students who entered as reactors. Observations on students of nursing revealed almost identical findings. Reviewing the observations on our entire group of students of nursing and medicine, we have been unable to find any significant difference in the development of the chronic reinfection type of tuberculosis between those who entered as reactors and those who became reactors while in school.

A third reason could be a difference in the disease itself. No doubt erythema nodosum occurs more frequently in Scandinavia among persons who recently became allergic than happens in our area. Moreover, we have rarely seen the adult just infected in whom progressive pulmonary tuberculosis immediately developed, as is reported to occur often in Scandinavia.

Demonstrable lesions and conditions that are in evidence about the time allergy can be elicited and those that appear in the next year or so have constituted an extremely small part (not more than 3 per cent) of the lesions which develop in this vicinity (chart 1). This is the only group of lesions for which significant claims have been made for BCG.

UNDUE RELIANCE ON X-RAY FINDINGS

Unfortunately, in nearly all of the reports made to date on morbidity among both vaccinated and controls, the diagnoses of chest conditions have been made largely from x-ray shadows alone. Inasmuch as x-ray shadows are never pathognomonic, all diagnoses are subject to honest questioning unless the presence of tubercle bacilli has been demonstrated by culture or animal inoculation. Deaths reported by various authors as due to tuberculosis in both the vaccinated and the controls constitute a relatively small total number. Usually no statement has been made as to whether diagnoses were confirmed by necropsy and, if so, whether bacteriological evidence was required. Without the above confirmation, errors in diagnosis may have been frequent.

There is no evidence that BCG has any influence on the occurrence of lesions that often develop two or more years after the initial invasion with tubercle bacilli. So far, only Heimbeck has reported on such observations (1947 and 1948). He traced the nurses who had graduated from the Uleval Hospital, Oslo, Norway, since his studies began. This included those who had entered the school of nursing as reactors to tuberculin, those who entered as nonreactors and accepted BCG and those who refused it. He found no important difference among the three groups.

Chart 1.—*Tuberculous manifestations that occur* about the time a high degree of allergy is attained, regardless of age, from the first infection of the human body with tubercle bacilli. These conditions, including erythema nodosum (*1*), enlarged hilar shadows (*2*), pleurisy (*3*), meningitis, miliary disease and tuberculous pneumonia (*4*), appear promptly in only a small percentage of persons who become infected and constitute about 3 per cent of the tuberculosis problem among the groups we have observed. The *reinfection forms of tuberculosis* (*5*) *that* later occur among tuberculin reactors constitute the remaining 97 per cent of our problem. Claims that BCG will control 60 to 80 per cent of tuberculosis apply only to the 3 per cent of tuberculous manifestations that occur within a year or so after allergy can be elicited by the tuberculin reaction.

Thus, claims for the efficaciousness of BCG would apply to only about 3 per cent of illness and death from tuberculosis in our area. The remaining 97 per cent have not been investigated, and evidence is lacking that this form of vaccination will be helpful in them.

NO DEPENDABLE IMMUNITY IN TUBERCULOSIS

As our work on fundamental methods of controlling tuberculosis progressed, we were unable to see any premise for attempting to produce artificial immunity because there was no satisfactory evidence that an attack of tuberculosis had ever resulted in dependable immunity. Wherever chronic tuberculosis causes death, in addition to the killing disease found at necropsy, there are always other lesions of long standing. If these lesions result in dependable immunity, why do so many die from tuberculosis? Why is this disease of such antiquity, now the first among all diseases as a cause of incapacity and death among the people of the world as a whole? If everyone had an attack of smallpox prior to the age of 18 years, there would be practically no illness or death from this disease during the remainder of life. Yet, in areas of the world where practically everyone has had an attack of tuberculosis prior to the age of 18 years, clinical tuberculosis exists almost in epidemic form, incapacitating and killing great numbers in the remainder of life's span.

In the early days of our work we accepted the universal teaching that tuberculin reactors were immunized and advised them that they were in no danger of later having clinical tuberculosis. Many of them were apparently healthy children; but, when as young adults a considerable number returned with contagious advanced tuberculosis, we discovered that what we had taught was only theory based on speculation and personal opinions.

Between 1921 and 1941 we had under observation 18,856 children. During the first five years of this period there were 1,033 reactors who were completely examined, of whom 15 already had reinfection type of pulmonary tuberculosis and 39 others acquired it prior to 1941. Eighteen others among the original reactors had on first examination or subsequently acquired extrathoracic reinfection type of tuberculosis.

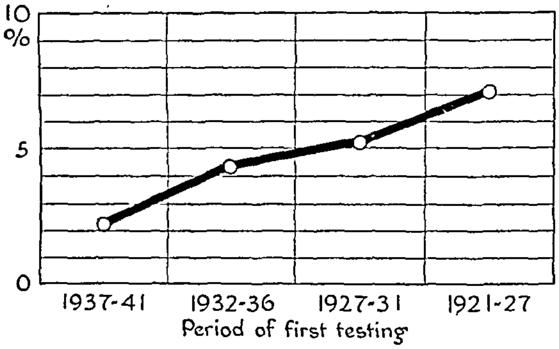

Chart 2.—Incidence of reinfection type of tuberculosis observed among tuberculin reactors. This type of disease increases with the number of years of observation after the infection is first detected.

By 1941 this study revealed that among those who reacted to tuberculin between 1921 and 1926, 7.1 per cent had at the time of the first examination or subsequently acquired the reinfection type of pulmonary or extrathoracic tuberculosis; among children first examined between 1927 and 1931, this percentage was 5.9; among those examined between 1932 and 1936 this percentage was 4.3; among those between 1937 and 1941 this percentage was 2.2. Thus, the longer tuberculin reactors remained under observation, the higher the percentage who developed clinical forms of tuberculosis (chart 2). Similar observations on other groups of people during and since this period convinced us that whatever immunity may develop in tuberculosis is not dependable or predictable.

The human body manifests its best defense against the tubercle bacilli of the first infection. When 1,000 persons (regardless of age) are infected for the first time and the tissues become hypersensitive to tuberculoprotein, a few soon have such symptoms as fever and other allergic manifestations. However, when the same 1,000 persons are reinfected exogenously or endogenously, after the tissues are allergic one may expect both acute and chronic forms of clinical tuberculosis in a considerable number within the next few decades. Acute forms of reinfection type tuberculosis, such as meningitis, miliary disease and pneumonia, may appear soon after allergy is well established. They may also emerge at any subsequent time. As the years pass, the chronic forms of disease loom. Bogen states that clinical tuberculous lesions subsequently develop in about one-half of infected persons, and that more than 10 per cent of these persons ultimately die from tuberculosis. Thus, dependable immunity is not in evidence.

NO CRITERION FOR IMMUNITY AVAILABLE

When our studies began, in 1920, several phenomena were believed to be criteria for immunity. A large amount of fibrous tissue seen on roentgenograms or at necropsy was thought to be a display of immunity. In reality, this is only a response to irritants, some of which cause more fibrosis than do the tubercle bacilli. Silicon dioxide is a good example. Deposition of lime salts was thought to be an excellent indication that immunity or resistance to tubercle bacilli had developed to a high degree. Now we know that this phenomenon is not specific for any disease. It occurs in necrotic tissue or pent-up pus from any cause. In some areas of this country more calcium deposits in the lungs and regional lymph nodes are caused by fungus infections than by tubercle bacilli.

A long interval—from months to decades—occurs between exposures to clinical tuberculosis and the appearance of illness. In many persons illness never develops. These facts were erroneously interpreted as evidence of immunity when, in reality, they indicate only that the defense mechanism has walled off the tubercle bacilli as it would silica particles. However, should the descendants of these bacilli later escape and invade allergic tissues, or should exogenous reinfection occur, there is no dependable immunity to prevent the formation of clinical lesions. For example, children who had been in intimate contact with their tuberculous mother and who appeared well long after her death were thought to have become immune; but observation revealed that during the teen ages, twenties, thirties and even later in life, enough of them fall ill from clinical tuberculosis to give the clinician no confidence in the presence of dependable immunity.

The tuberculin reaction was also regarded as a criterion of immunity. However, our observations revealed that it was only the reactors to tuberculin, children and adults alike, in whom clinical tuberculosis developed. Moreover, nearly every person in other groups of people with proved tuberculosis was allergic to tuberculoprotein. Thus it became obvious that tuberculin reactors at any age are potential patients with clinical tuberculosis. This completely shattered our confidence in the tuberculin reaction as a criterion of immunity.

Rich made an intensive study of this subject and concluded that there is no law of parallelism between hypersensitivity and acquired resistance in tuberculosis. With reference to BCG, Dubos says:

> The development of a positive tuberculin test is universally used as a criterion that the vaccine has "taken" but, unfortunately, as already pointed out, the relation of tuberculin allergy to immunity is one of the most obscure aspects of the pathogenesis of tuberculosis.

He points out that a test devised to measure streptococcal allergy does not measure resistance to streptococcus infection and by analogy the tuberculin test does not necessarily reflect immunity to tuberculosis.

Dubos says:

> . . . it is urgent that techniques be developed for the measurement of true immunity (not tuberculin allergy) in order that the BCG immunization program can be intelligently controlled. Unfortunately we are still in complete ignorance of the immunological mechanisms, humoral or cellular, which bring about immunity to tuberculosis. It is not possible, therefore, to devise any laboratory tests that would control the effectiveness of BCG vaccination.

Inasmuch as no test has been devised, we still do not know how much or how little immunity is acquired by any person. All we know with certainty is that whatever immunity develops is not dependable. Most persons who have reported results of studies on BCG and vole tubercle bacillus have observed that vaccination with these living bacilli is no more efficacious than natural infection with virulent tubercle bacilli. Since natural infection has failed to solve the tuberculosis problem, it does not seem reasonable to believe that it will be resolved by something no better. The reaction to tuberculin is only a test for allergy.

ALLERGY UNDESIRABLE

When it became obvious that allergy is not a criterion of immunity but that it is a prerequisite for the development of destructive forms of tuberculosis, we looked upon the tuberculin reaction as undesirable and therefore to be avoided if success in tuberculosis control was to be achieved. We could see no reason for deliberately producing tuberculosis with its accompanying hypersensitivity to tuberculoprotein by administering living tubercle bacilli of reduced virulence. To us this meant establishing the prerequisite for reinfection type of tuberculosis should infection with virulent tubercle bacilli occur. It was our contention that by adequate fundamental control methods we could gradually but surely prevent allergy by protecting against infection with tubercle bacilli, thus leading to the eradication of tuberculosis.

In 1925, Krause said:

> Accordingly the allergic reaction is seen to be responsible for all of the acute manifestations of tuberculosis and when so considered, it must be viewed as a potent contributor to pathogenesis. Human beings pass as perfectly well as long as they hold their tuberculous infections asymptomatic, inactive. But they are allergic, and any discharge of sufficient focal material to a new place will render them immediately ill because of the allergic reaction that ensues promptly.

This also applies to tubercle bacilli from exogenous sources.

Allergic tissues have the ability temporarily to fix or hold tubercle bacilli at or near points of lodgment. Apparently it is this fixing power which has deceived so many physicians for decades. After allergy has been artificially created and virulent tubercle bacilli are introduced, their dissemination is temporarily retarded. For example: Krause introduced tubercle bacilli subcutaneously into the groins of nonallergic guinea pigs and found that some had traveled to the lungs, tracheobronchial lymph nodes and spleen in four days or less. These animals died from tuberculosis in approximately three months. The same experiment conducted with a group of allergic guinea pigs showed that bacilli had not reached the lungs, tracheobronchial lymph nodes and spleen until three weeks to 30 days, and these animals did not die from tuberculosis until 10 to 11 months. It was the temporary fixing power of the allergy which delayed the movement of the tubercle bacilli in the allergic animals. However, the ultimate effect was the same. It is this same phenomenon which has deceived all who have attempted to produce immunity by rendering tissues allergic.

HARMLESSNESS OF BCG NOT PROVED

Although Calmette strongly maintained that BCG is harmless, we have not been able to believe that any living bacillus that was once so virulent as to cause death of animals in four to six weeks can be trusted when many millions are injected into a human body. It is now known, contrary to Calmette's belief, that the virulence of BCG changes materially. Holm says, "It is very important to keep the virulence of the BCG strain at the proper level and to watch closely the variations of its virulence." Jensen pointed out that the virulence of BCG changes and that if the strain becomes too virulent abscesses develop among those who receive it, with alarming effects. On the other hand, virulence has been found to decline so that it does not even produce allergy. Considerable effort is put forth to produce BCG of just the "right" virulence and then rush it, often by airplane, to the children who are to receive it. Not enough thought is given to how virulence of these living bacilli may change after they have been introduced into the bodies of children.

Dubos (1949) observed that three strains of BCG obtained from American collections differ significantly in their ability to produce pulmonary lesions in mice after intravenous injection. In discussing the importance of the physiological state of animals used for study, he says:

> *Thus it has been shown at the Saranac Laboratory that the strain RIRV (in many respects difficult to differentiate from BCG) causes severe disease in the silicotic guinea pig but not in normal animals. It has also been found in our laboratory that one of the BCG strains commonly used for immunization can cause severe pulmonary disease (and sometimes death) when injected in sufficient amounts into mice maintained on deficient diets.*

These facts we view with great alarm. Who knows what the physiological state is of the millions of children receiving BCG at this time. Concerning this, Dubos says:

> *It is even conceivable that many of the classes of human beings who are most dangerously exposed to tuberculosis (for example, those living under conditions of great economic stress with inadequate food supplies) may be those least capable of responding satisfactorily to immunization procedures.*

When BCG is administered subcutaneously, large abscesses at the site of injection and suppurating regional lymph nodes often occur. To avoid such extensive disease caused by BCG, Rosenthal in 1938 advocated the multiple puncture method of administration. His hope was only partially fulfilled, as such lesions still occur. For example, C. Blanch and co-workers (1948) reported 12 cases of suppurating lymph nodes complicating the administration of BCG by the puncture method. The reactions consisted of local single or multiple abscesses, infarction of lymph nodes, abscess formation and fistulization. These characteristic tuberculous abscesses ruptured and drained for many months. Sometimes they appeared eight or more months after BCG was administered. Every administration of BCG resulting in a so-called take causes necrosis in at least the deeper layers of the skin with corresponding lesions in the regional lymph nodes.

G. Wiek (1948) reported on the various lesions found in 15 children from 5 to 14 years of age who received BCG in 1945 and 1946. Pulmonary infiltrations were seen in nine; pleurisy with effusion in four; bronchial lymph node tuberculosis in one; and elimination of bacilli without demonstrable pulmonary focus in one.

The statement is made that BCG is harmless and that no case has been reported in which it has regained virulence in man. There is a sparcity of evidence in the literature to support this statement. The number of lesions removed for biopsy or at necropsy from vaccinated persons who fell ill or died from tuberculosis to determine this point apparently is almost nil.

In animals or people in whom subsequent to inoculation with BCG progressive disease has developed, one might expect that typing of the organism would promptly reveal its identity. Unfortunately, this has not been found so simple. For example, with Dreyer's virulent BCG strains, Griffith could classify them only as mammalian and thus could not determine whether they were of human or bovine type. Holm said (1946):

> After staying in the human organism for some time the bovine type of the tubercle bacilli will change in character in such a way as to be diagnosed as the human type.

UNWARRANTED CLAIMS AND PREDICTIONS

Von Behring (1902) stated that his vaccines would soon render tuberculosis a disease of only historic interest. However, in about one decade his method was discarded.

It has been stated recently that BCG is capable of controlling 60 to 80 per cent of tuberculosis. Evidence indicates that in our area this, if proved, would apply to only about 3 per cent of our problem.

Concerning tuberculosis in Japan, it was recently said: "The BCG immunization program will in the future prevent the occurrence of most of the cases of clinical tuberculosis." Such a result has never been approached anywhere by the use of a vaccine. In Japan the annual death rate from tuberculosis is reported to have decreased from 280 per 100,000 to 181.1 in recent years. This was attributed largely to the use of BCG and would be convincing evidence were it not that similar decreases have occurred in other parts of the world in the absence of BCG. Levine says:

> We are told that in Buenos Aires the tuberculosis death rate in children under the age of 15 years decreased some 72 per cent between 1924 and 1944. This decrease was attributed to BCG. This would appear to be convincing evidence were it not for the fact that during these same years the tuberculosis death rate in New York City decreased about 95 per cent without the use of vaccine.

BCG HIGHLY CONTROVERSIAL

After more than 40 years of use of BCG in animals and more than 25 years in humans, no agreement has been reached among its proponents with reference to what constitutes a good vaccine, how it should be administered, what comprises a "take" or how long it is potent. Some physicians believe that persons should be extensively exposed to contagious tuberculous patients immediately after their tissues have been made allergic by BCG, while others contend that every effort should be made to protect against reinfection with virulent bacilli for all time after BCG has been administered. Thus, BCG lacks the qualities necessary to serve the purpose that its proponents desire. If it had been proved efficacious, its proponents should have agreed on a standard procedure; moreover, its past and present opponents would have accepted it. The medical profession has never been hesitant in accepting diagnostic, therapeutic or preventive measures of proved value. Good examples are the roentgenogram in diagnosis, insulin in therapy and smallpox vaccine in prevention. At this moment there is probably nothing in medicine as highly controversial as the value, if any, of BCG. Palmer, of the United States Public Health Service (1949), says:

> First it must be admitted in clear and unequivocal terms that strict scientific proof of the efficaciousness of BCG vaccination in the control of human tuberculosis is not available.

TOO LITTLE TO GAIN—TOO MUCH TO LOSE

Analysis of the scores of reports on the use of BCG has convinced us that any possible gain would be far too slight to justify its administration to our children, students or older adults. Tuberculosis (within a year or so after infection occurs) in which benefits are claimed from BCG constitutes only about 3 per cent of our problem. There is a total lack of evidence of any efficaciousness in the remaining 97 per cent. Even in the 3 per cent group, no one has claimed complete protection. All admit that illness and death occur among the vaccinated. Thus, even in this small group (3 per cent) one could never hope to eradicate tuberculosis by the use of BCG.

Our program of tuberculosis control would have suffered great loss had BCG been adopted. The mere finding that the skin is allergic to tuberculoprotein is proof positive of the presence of at least primary tuberculous lesions, and in most cases these lesions contain living tubercle bacilli. Therefore, the tuberculin test is our most effective weapon against tuberculosis. In diagnosis it is indispensable. It is by far the finest epidemiological agent, and it is the only accurate method of determining with reasonable promptness the effectiveness of tuberculosis eradication measures.

BCG does not prevent subsequent infections with virulent tubercle bacilli. However, it renders the tissues allergic to tuberculoprotein so that they react to tuberculin, thus depriving the individual of the inalienable right to have the presence of virulent tubercle bacilli detected promptly if and when they invade his body. Current attempts to differentiate between infections with BCG and virulent tubercle bacilli by color, degree of reaction or other means do not seem promising in the light of variations in virulence of BCG.

It is contended that only experts, individually or in teams, can satisfactorily administer BCG. This eliminates the family physicians—the general practitioners—who are so needed to solve the tuberculosis problem everywhere. In our program general practitioners have done a large volume of the work. To eliminate them by introducing a procedure that they cannot properly use and depriving them of their most potent weapon, the tuberculin test, would be disastrous.

When the physician uses the words "vaccination" and "immunity," the public thinks of almost total immunity, as obtains in smallpox. Therefore, when these words are used in association with tuberculosis, a false sense of security is transmitted to the individual and the public, which may result in relaxation of proved sanitary measures. For example, persons found to have contagious tuberculosis have refused to leave their homes because they had been told that their children could be immunized against the disease. Again, those already in institutions have insisted upon leaving because they believed the vaccine would protect their children against tubercle bacilli.

The idea is extant that vaccination with such substances as BCG will so completely control tuberculosis that the need for sanatoriums will soon vanish. This is said already to have influenced legislators and others who would ordinarily promote and support repairs and additions to existing hospitals and sanatoriums and the construction of new ones when needed.

CONTROLLED STUDY IMPERATIVE

Since Calmette opposed a controlled study in France in the early 1920's, no such investigation has been conducted with sufficient care to rule out all other factors or long enough to justify dependable conclusions regarding the efficaciousness of BCG. In fact, several proponents of its use now oppose such a study on the ground that time should not be lost while waiting for facts. This is an example of enthusiasm having outrun not only due caution but judgment as well. With our present lack of knowledge of immunity in tuberculosis, it is doubtful whether such a study is possible. Dubos, of the Rockefeller Institute for Medical Research (1949) said:

> There have been endless controversies concerning the dangers and effectiveness of immunization with the BGG vaccine. Surprisingly enough, however, little has been said or written concerning the immunological basis and the technical problems involved in the preparation of the vaccine or the measurement of its protective efficacy. Opponents as well as proponents of BCG vaccination seem to accept implicitly that the technical procedures advocated by Calmette and his associates for growing the microorganism, preparing suspensions of it and assaying the development of immunity, are fundamentally adequate and need not be modified except in detail. This is a questionable assumption and there is much reason to suspect that many of the controversies elicited by BCG vaccination cannot be settled until a number of bacteriological and immunological problems have been solved. . . . It is highly desirable, therefore, that BCG preparations be standardized in terms of their ability to induce immunity against tuberculous infection. Surprisingly enough, there is as yet no well defined technique for such an assay.

These statements from such excellent authority strongly suggest that before a dependable controlled study is possible the entire subject of immunity in tuberculosis ought to be referred to competent bacteriologists and immunologists for the determination of facts that we do not now possess. The Oxford University investigators of the vole tubercle bacillus vaccine said: "To plan a controlled experiment in tuberculosis vaccination in man is a matter of so much difficulty as to be virtually impossible." Medlar states: "The difficulties of assessing the value of vaccination with BCG in experimental animals under controlled conditions emphasizes the greater difficulties encountered in experiments in man because of the existence of uncontrolled and uncontrollable conditions."

Although the handicaps to an assessment of facts are obvious, the Division of Tuberculosis of the United States Public Health Service called a Conference on BCG in September, 1946. On recommendation of this conference, arrangements were made to set up the best controlled study possible on a limited number of persons and to employ an adequate staff in order to make sure that every person was kept under close surveillance throughout the duration of the project. It was realized that this would need to be continued for 25 years and probably longer before the desired facts about BCG would be obtained. This study is now in progress, and it deserves the unstinted support of the medical profession everywhere, since it promises the best that can be done under existing circumstances.

Much of the present enthusiasm for BCG stems from a few workers in Scandinavia. In fact, Holm, through the Danish Red Cross, has directed teams in many nations in Europe, Asia, Central America and elsewhere. The mission of these teams is not only to administer BCG to millions of children and young adults but also to convince professional workers and the public everywhere of its efficaciousness. The tuberculosis situation in Denmark is comparable in most respects to that of Minnesota. The population of the two areas is nearly equal—approximately 3,000,000. A preponderance of Minnesotans are of Scandinavian ancestry. Fundamental control measures have been similarly practiced. In neither Denmark nor Minnesota was there increase in tuberculosis mortality during World War II. The significant difference is that BCG has been used in Denmark since 1927, sparingly at first but extensively over the past decade. Thus we welcomed the opportunity to compare results in Denmark and Minnesota.

In Denmark there has been an almost continuous decrease in mortality (except during World War I) since 1906. The mortality rate in 1949 was 19 per 100,000. The mortality rates graph shows no indication of sharp decrease with the use of BCG in Denmark. Thus, a fair question is whether the fundamental methods that were operating so effectively prior to the BCG era are not actually the factors responsible for the continued decrease during this era. Holm states that at the age of 14 years, about one third of the Danish population reacts to tuberculin while two thirds are reactors at 20 to 23 years.

RESULTS FROM OUR FUNDAMENTAL METHODS ALONE

As our work progressed, the theory that primary infection immunizes was frequently emphasized and it was often said that protecting children against infection would soon lead to so many "nonimmune" adults that should they then become infected they would be swept away in vast numbers by tuberculosis. Theorists argued that producing dairy products without the bovine type of tubercle bacilli would deprive children of immunity. The theory proved to be untenable. As tuberculosis among cattle was controlled almost to the point of eradication throughout the state, there followed a decline in mortality, morbidity and infection attack rates among human beings. As the infection attack rate was further decreased by protecting children and adults alike from human type tubercle bacilli, there also followed a corresponding decrease in morbidity and mortality from tuberculosis.

As uninfected children attained adulthood they presented no tuberculosis problem. Those, such as students of nursing and medicine, who became infected as adults, controlled primary lesions in the same manner as those who had been infected in childhood. We have not observed that primary infections in adults are more dangerous than in children or that a considerable number of the cases of tuberculosis in adults are closely related in point of time to primary infection. Thus, the theory that producing "virgin soil" in human beings would later result in disaster has proved to be a myth.

Theorists maintained that in such situations as obtain in schools of nursing and medicine and in general hospitals it was impossible to prevent exposure to tubercle bacilli. Hence the term "unavoidable exposure" was coined. When the fundamental method of control was applied, it was found practically as effective in such institutions as in the general population. In our school of medicine, in which up to 65 per cent of those who entered as nonreactors to tuberculin became reactors and 4 to 10 per cent acquired demonstrable lesions before graduation, the infection incidence was reduced to 3 per cent, and seven years have elapsed with development of a demonstrable lesion in only one student.

In a school of nursing from which no student had escaped infection and in which from 12 to 19 per cent presented demonstrable lesions before graduation, the infection attack rate was reduced to zero in the graduating class of 1945, and in only one student has a lesion been detected by roentgen shadow in the past seven years. No school of medicine or nursing has reported comparable results from BCG.

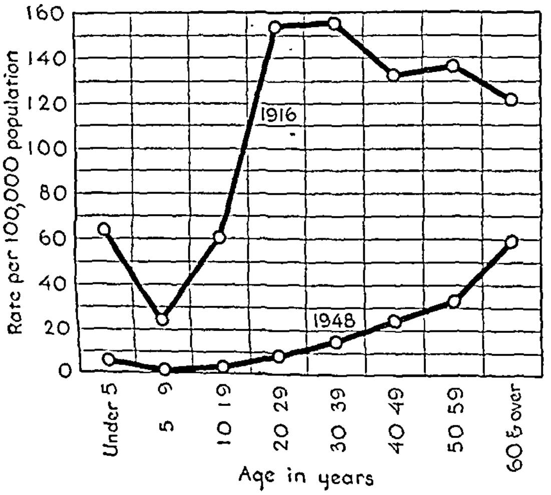

Chart 3.—Marked reduction in mortality rates among persons at various ages between 1916 and 1948. This was accomplished by fundamental methods of tuberculosis control in the absence of BCG.

American Indians have been spoken of as highly susceptible and exposure among them is "unavoidable." We have not found Minnesota Indians more susceptible than Caucasians, nor has infection been unavoidable among them. They have responded to fundamental control methods exactly as have the Caucasians. What was thought to be susceptibility was the result of neglect. When fundamental methods were instituted, the response was remarkable. For example, in 1937 there were 64 deaths (mortality rate 529.2) among our 12,500 Indians, but in 1949 only 9 (rate 71.8) died. Although BCG has been extensively used among Indians in some states, we know of no result comparable to that achieved in this state where it has not been employed.

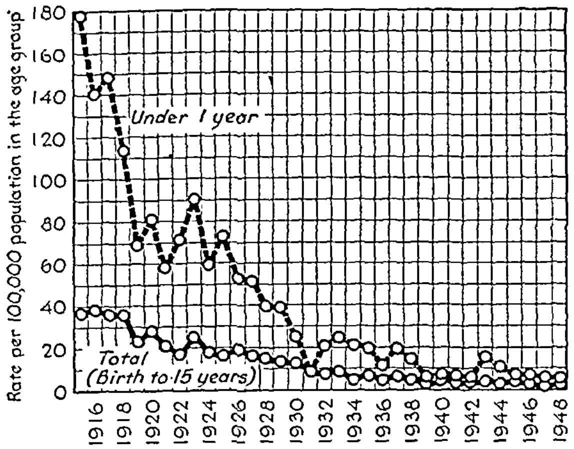

Chart 4.—Marked decrease in the tuberculosis mortality rates among children from 1916 to 1948. This was accomplished without the use of immunizing agents.

Application of the same fundamental methods accomplished other excellent results. For example, by 1935 the veterinarians had tuberculosis among cattle so well controlled that the entire state was accredited. In 1949 only 0.09 per cent of the cattle reacted to tuberculin.

Waiting lists in sanatoriums decreased until many vacant beds now exist because of the lack of patients. There was a tumbling down of mortality, morbidity and infection attack rates from year to year (Chart 3). In this state the tuberculosis mortality rate dropped from 106.1 (2,400 deaths) in 1916 to 13.6 (410 deaths) in 1949. Among the 410 who died that year, 63.2 per cent were 50 years old or over and 31.5 per cent were 65 or older.

In 1916 there were 68 deaths (mortality rate 140.4) among babies under 1 year old. This was reduced to 3 deaths (rate 6.3) in 1948, and to 2 (rate 4.4) in 1949. In 1916 among children from birth to 15 years 275 (rate 38.3) died of tuberculosis, but only 19 (rate 2.6) died in 1948 and 9 (rate 1.3) died in 1949 (Chart 4). While 268 (rate 60.4) from 10 to 19 years died in 1916, only 14 (rate 2.8) died in 1948, and 7 (rate 1.4) died in 1949.

In the entire state the infection attack rate has been reduced to less than 0.3 per cent per year. By 1944 in Minneapolis only 7.7 per cent of grade school children had primary tuberculosis (tuberculous infection), against 47.3 per cent in 1926. By 1948 there were large numbers of schools in rural counties in which no child reacted to tuberculin. Among high school students in the largest city approximately 12 per cent and in other parts of the state rarely more than 8 and often less than 4 per cent now react to tuberculin. By 1945 only 6.4 per cent of students entering the University of Minnesota were infected with tubercle bacilli.

SUMMARY AND CONCLUSIONS

Fundamental methods of controlling tuberculosis consist of treating it as a contagious disease and thus preventing bacilli from invading the tissues of people and animals. This necessitates the use of the tuberculin test, x-rays, the microscope, culture mediums, animal inoculation and other procedures, as well as isolation and treatment of patients with contagious disease in hospitals and sanatoriums. Scores of physicians have long sought methods of artificially produced dependable immunity for tuberculosis. None have succeeded, probably because natural infection with virulent tubercle bacilli does not result in dependable immunity. BCG is a living bovine type bacillus of reduced virulence. In culture mediums its virulence fluctuates significantly. When introduced into human tissues, it causes tuberculous lesions which may come under control in a few months. In some cases abscesses develop and regional lymph nodes discharge pus for many months. BCG causes progressive and killing tuberculosis in silicotic animals as well as those on deficient diets. The amount of scientific work reported to prove its harmlessness in man is almost nil. BCG or vole tubercle bacillus vaccine renders the tuberculin reaction useless as a diagnostic and epidemiological agent and diminishes or even eliminates much necessary public support by creating a sense of false security in the minds of the people.

The tuberculin reaction is not a criterion of the presence of immunity. This reaction indicates only the presence of allergy, which is a prerequisite for development of clinical forms of tuberculosis. No method of identifying or measuring immunity or resistance to tubercle bacilli is available. Most observations on BCG have been limited to those conditions that occur within a year or two after allergy is established by natural infection. Here it is said to be 60 to 80 per cent efficacious. These conditions constitute only about 3 per cent of our problem. There is no evidence that it has any value in the remaining 97 per cent.

No scientific adequately controlled study of BCG has ever been conducted over a sufficient period of time to justify conclusions regarding its efficaciousness. It is doubtful whether such a study is possible in persons living in their homes. However, the serious effort now being made by the Division of Tuberculosis of the United States Public Health Service deserves unstinted support of the medical profession.

The use of fundamental methods exclusively over the last 30 years has resulted in control of tuberculosis among our students of nursing and medicine, American Indians, the general public and domestic animals that has never been remotely approached anywhere by the use of an immunizing agent. These methods when properly executed are sure of accomplishment. At the present time they afford our only hope of eradicating tuberculosis.

SYPHILIS AND GONORRHEA AS CAUSES OF BLINDNESS

A STUDY OF PERSONS DECLARED LEGALLY BLIND IN OHIO

Charles R. Freeble Jr., M.D.
and
James F. Donohue, M.P.H., Columbus, Ohio

This paper is a report of some findings concerning the role of syphilis and gonorrhea as etiological factors among persons declared legally blind in Ohio. Also considered are other aspects of syphilis and gonorrhea in blindness, including the topographical and pathological classifications of those persons whose blindness was caused by venereal disease, together with race and sex distribution of the venereal blind and observations on the age at which such persons become blind.

Financial assistance and vocational rehabilitation for blind persons in Ohio is a function of the Ohio Department of Welfare. Through the cooperation of that department and with the assistance of its Division of Research and Statistics, basic statistical data presented in this study were especially tabulated at our request and were made available to the Division of Communicable Diseases of the Ohio Department of Health. The tables presented in this study were constructed by us from the special tabulations mentioned above. We were specifically interested in bringing to light all possible information related to the role of venereal disease in blindness. The statistics of the Ohio blind are tabulated according to the standard classification of causes of blindness as recommended by the Committee on Statistics of the Blind, jointly sponsored by the American Foundation for the Blind and the National Society for the Prevention of Blindness.

When an Ohio resident applies for financial aid, he is examined by a local ophthalmologist, who reports the results of the examination on a standard form. The ophthalmologist's report is then reviewed by a consultant ophthalmologist retained by the state, and a decision is made as to whether the applicant is legally blind and entitled to financial assistance. The definition of legal blindness in Ohio is as follows: "Legal blindness is said to exist in an individual who with his better eye after correction has 20/200 vision or less, or has his field of vision reduced to a diameter of less than 20 degrees. It is also said to exist in any individual who after the removal of the lens from his eye has 20/70 vision or less."

Chief, Division of Communicable Diseases, Ohio Department of Health (Dr. Freeble).

Health Program Representative, Venereal Disease Division, United States Public Health Service (Mr. Donohue).

This definition was adopted by the Ohio Department of Welfare from certain standards suggested in the "Manual on the Use of the Standard Classification of Causes of Blindness" as published by the Committee on Statistics of the Blind.

Table 1.—*Etiology of Blindness in Ohio by General Classification, Jan. 1, 1939 Through Dec. 31, 1948*

General Classification	No.
Infectious diseases	852
General diseases	650
Prenatal origin	502
Trauma	326
Neoplasms	73
Poisonings	24
Undetermined or not specified	4,015
	6,442

SYPHILIS AND GONORRHEA AS CAUSES OF BLINDNESS

In the 10 year period from Jan. 1, 1939 through Dec. 31, 1948, there were 6,442 persons declared legally blind in Ohio. Etiology by general classification is shown in table 1. It will be noted that the largest group in the general classes involves cases in which the etiology was undetermined or not specified. This general group includes "unknown to science," "undetermined by physician," and "not specified." In many of these cases in Ohio, the blind person reported for his first examination many years after the onset of the condition that caused his blindness, and the examining ophthalmologist was unable to determine the etiological basis. However, this group also includes persons in whom the physician either did not take the trouble to establish a diagnosis or, if he did, failed to report his findings on the examination form. Other studies in blindness have been confronted with this same problem of having many cases of undetermined etiology.

When the 4,015 cases with undetermined etiology are deducted from the total, there are 2,427 cases of legal blindness in Ohio in which the cause was determined. Among the cases with known causes, infectious diseases were responsible for the greatest number, namely, 852 cases. Of the total number whose blindness was caused by infectious diseases, syphilis was the etiological factor in 507 cases, which represents 59.5% of all legal blindness due to infectious diseases (table 2). Thus it is evident that among presumably preventable diseases causing blindness in Ohio, syphilis leads all others. Table 2 shows the total 852 cases of legal blindness caused by infectious diseases, with the number of cases contributed to the total by each specific disease.

Table 2.—*Blindness in Ohio from Specific Infectious Diseases, Jan. 1, 1939 Through Dec. 31, 1948*

Syphilis	507 *
Trachoma	99
Ophthalmia neonatorum	68 †
Tuberculosis	50
Meningitis	23
Measles	15
Septicemia	14
Smallpox	6
Scarlet fever	5
Diphtheria	5
Gonorrhea	2
Other infec[illegible] specified	58
	852

* Of the 507 cases of syphilis, 35 cases were specified as "congenital syphilis," 31 as "acquired syphilis," and 441 as "syphilis—type not specified."

† Includes 23 cases specified as gonococcal, 40 type not specified, and 5 other types specified.

When only those cases are considered whose blindness was definitely attributed to syphilis, we find that the 507 syphilitics comprise 7.9% of the total 6,442 cases, which include the 4,015 cases with undetermined or unspecified etiology. From another point of view it may be considered that the 507 cases with syphilis account for 20.9% of the total 2,427 legally blind among whom the etiology was determined. It is also reasonable to assume that a considerable percentage of the 4,015 cases whose etiology was undetermined was caused by syphilis. If the assumption is made that the distribution of etiological factors among the 2,427 cases of known etiology is a good sample of the distribution of cases among the total number of legally blind in Ohio, one could arrive at the conclusion that about one-fifth of all blindness in the state is caused by syphilis. The validity of such an assumption has several aspects. Some ophthalmologists feel that syphilis is probably underreported. Cowan and English,[1] for example, in discussing their series of 31,352 eyes, in which the etiology was determined in 20,763 eyes, state: "We have 10,732 cases in which syphilis might have been an etiologic factor, yet it is noted as a factor in only 1,484 reports." On the other hand, it may be argued that laboratory tests for syphilis are simple, fairly accurate, and in wide use among physicians and that most syphilis among blind persons is diagnosed. Another interesting fact in the literature concerning this aspect of the role of syphilis in blindness is found in Berens' and Goldberg's [2] statement "laboratory examinations showed that Wassermann tests were made in only 2,237 (37.5%) of the 5,969 cases in which the diagnosis was an eye disease of possible syphilitic origin."

Table 3.—*Ten Leading Specific Causes of Legal Blindness in Ohio, Jan. 1, 1939 Through Dec. 31, 1948*

Syphilis	507 *
Prenatal origin	502
Diabetes	331
Trauma	326
Vascular disease	147
Trachoma	99
Neoplasms	73
Ophthalmia neonatorum	68 †
Tuberculosis	50
Poisonings	24
	2,127

* Of the 507 cases of syphilis, 35 cases were specified as "congenital syphilis," 31 as "acquired syphilis," and 441 as "syphilis—type not specified."

† Includes 23 cases specified as gonococcal, 40 type not specified, and 5 other types specified.

The relative importance of gonorrhea among infectious diseases causing blindness is not apparent. As may be seen in table 2, ophthalmia neonatorum as a disease entity ranked third among the infectious diseases causing blindness. Of the 68 cases ascribed to this cause, 23 were specified of gonococcal origin, and five to other specific types. The remaining 40 cases were classified as "ophthalmia neonatorum—type not specified." The preponderance of gonorrhea among those cases in which type was specified, coupled with past medical experience and the fact that in past nomenclature the terms ophthalmia neonatorum and gonorrheal ophthalmia were practically synonymous, would lead us to believe that a substantial percentage of the 40 cases in which type was not specified was in fact gonococcal in origin. Nevertheless, when the 23 cases specified as of gonococcal origin are considered alone (which is, of course, a minimum figure), gonorrheal ophthalmia appears as an important cause of blindness due to infectious diseases. On the other hand, it should be noted that gonorrhea, excluding gonorrheal opththalmia neonatorum, was responsible for only two cases of blindness during the 10 year period.

---

[2] Berens, C., and Goldberg, J. A.: Syphilis in Relation to Prevention of Blindness: A Study of 100,000 Case Records, J. A. M. A. **109**: 777 (Sept. 4) 1937.

The 10 leading causes of legal blindness (where the cause was determined and specified) are shown in table 3. Syphilis ranks first among the 10 leading specific causes of blindness in Ohio. It is striking to observe that infectious diseases, which are presumably preventable, account for four of the 10 leading causes of blindness. It may be noted also that the ophthalmia neonatorum group, which includes at least 23 cases of gonococcal origin, ranks eighth among the 10 leading causes. As an observation on "prenatal origin," which ranks second in table 3, Berens, Kerby and McKay [3] in their study on blindness among 27,002 school children indicated that syphilis is probably responsible for a large proportion of the blindness now classified as congenital or hereditary. If this latter point is true, blindness due to syphilis would loom even greater than is evidenced by the information at hand.

TABLE 4.—*Number and Percentage of Cases of Legal Blindness Due to Syphilis by Year, Jan. 1, 1939 Through Dec. 31, 1948*

Year	Total No. (All Causes)	No. Caused by Syphilis	Percentage Due to Syphilis
1939	677	78	11.5
1940	726	89	12.3
1941	732	56	7.7
1942	602	33	5.5
1943	468	14	3.0
1944	380	26	6.8
1945	443	22	5.0
1946	595	56	9.4
1947	701	46	6.6
1948	1,118	87	7.8
	6,442	507	7.9

Table 4 shows the number and percentage of cases of legal blindness due to syphilis by year from 1939 through 1948. In interpreting table 4, one should keep in mind that the percentage of cases caused by syphilis each year is a minimum figure, since each annual total includes many cases in which the etiology was undetermined or unspecified.

Despite approximately 10 years of intensive venereal disease control activities aimed primarily at syphilis, the table shows no consistent downward trend in the percentage of blindness due to syphilis. Although there was a downward trend during the first five years of the 10 year period, the minimum percentage was reached during 1943. Considerably higher percentages have occurred in each of the five years since 1943. The percentage of blindness due to syphilis from 1939 through 1943 was 8.4. The percentage for the five years from 1944 through 1948 was 7.3. Although the most recent five year average percentage was lower, the difference was not statistically significant. On the other hand, the 7.9% of blindness due to syphilis in the 10 year period under discussion was higher than that indicated by statistics available for several years prior to 1939, during which period syphilis was responsible for 7.1% of all blindness in Ohio (table 5). The latter difference was not significant either, however.

TABLE 5.—*Legal Blindness Caused by Venereal Disease in Ohio Before 1939 and During Jan. 1, 1939 Through Dec. 31, 1948*

Cause of Legal Blindness	Before 1939		1939 thru 1918		Both Time Periods	
	No.	%	No.	%	No.	%
All causes	3,137	100.0	6,442	100.0	9,579	100.0
All venereal diseases	252	8.0	532	8.3	784	8.2
Gonorrhea excluding ophthalmia neonatorum	3	0.1	2	0.03	5	0.05
Gonorrheal ophthalmia neonatorum	26	0.8	23	0.4	49	0.5
Syphilis	223	7.1	507	7.9	730	7.6

As to the role of gonorrheal ophthalmia neonatorum as a cause of blindness, the 23 cases in the 10 year period accounted for 0.4% of the total 6,442 cases. This represents a significant decrease as compared to the years before 1939 when gonorrheal ophthalmia neonatorum contributed 26 cases, or 0.8% of a total of 3,137 cases declared legally blind from all causes. There has been an even greater decrease in "ophthalmia neonatorum type not specified" since 1939. This classification (not shown on table 5 because the origin was not specified), which undoubtedly included many cases of gonococcal origin, decreased as the etiological cause of blindness from 3.1% of the total cases before 1939 to 0.6% in the 10 year period from Jan. 1, 1939 through Dec. 31, 1948.

TABLE 6.—*Comparison of Syphilis as an Etiological Factor in Blindness in Ohio and Other Areas*

Area	Total No. of Cases in Study	Cases with Etiological Factor Determined	Caused by Syphilis		
			No.	% of Total No. of Cases in Study	% of Cases with Etiological Factor Determined
Ohio	6,442	2,427	507	7.9	20.9
Pennsylvania [1]	31,352 *	20,763 *	1,843 *	5.9	8.9
Canada [4]	12,652	5,703	518	4.1	9.1
Massachusetts [5]	1,176	713	128	10.9	18.0
Minnesota [6]	768	563	84	10.9	14.9
Scotland (Brit. J. Ophth. *38: 381, 1946*)	7,297	7,150	730	10.0	10.2
Kentucky [8]	1,901	1,037	130	6.8	12.6
Texas (Texas State J. Med. *41: 519, 1946*)	6,106	1,742	411	6.7	23.6
	67,694 †	40,096 †	4,351 †	6.4 †	10.9 †

* These figures are based on the number of eyes, not the number of cases.

† Includes all cases (and eyes) in the eight studies.

It might be well to compare the Ohio figures with reported findings in other areas. Table 6 illustrates the various data concerning the percentage of all blindness due to syphilis as compared to all causes including undetermined etiology. This percentage ranges from 4.1% in the Canadian study [4] to 10.9% as determined in the

Massachusetts[5] and Minnesota[6] studies. The average percentage of blindness due to syphilis as compared to all causes, including unknown etiology, was 6.4 for the eight studies combined.

AGE, SEX, AND RACE FACTORS

This section is devoted to the age, sex, and race factors of persons in our series whose blindness was caused by venereal disease. The data presented represent all cases of legal blindness in Ohio whose medical records have been coded by the Department of Welfare. They include all the cases in the 10 year period previously discussed, plus cases from 1938 and before, as shown in table 5. Coding and punching under the standard classification of Statistics of the Blind was instituted in Ohio in 1938. At that time, the backlog of cases declared legally blind during 1938 and before were coded and punched according to the standard classification, but all these pre-1939 cases were grouped together in the category of "1938 and before." The exact year was not identified. The total number of cases of legal blindness in this period before Jan. 1, 1939, was 3,137 as shown in table 5. Of this early group, 223 (7.1%) were attributed to syphilis, 26 (0.8%) to gonorrheal ophthalmia neonatorum, 97 (3.1%) to ophthalmia neonatorum type not specified, and 3 (0.1%) to gonorrhea, excluding gonorrheal ophthalmia neonatorum. Addition of these pre-1939 data to the information previously discussed shows a total of 784 legally blind persons whose disability was caused by venereal disease among all persons declared legally blind for whom records were maintained. Inasmuch as "ophthalmia neonatorum type not specified" has an unknown percentage due to the gonococcus, this group is not included in the 784 cases.

TABLE 7.—*Race and Sex Distribution of 784 Cases of Blindness Caused by Venereal Disease, Before 1938 Through Dec. 31, 1948*

	White		Negro		Other		
Venereal Disease	Male	Female	Male	Female	Male	Female	Total
Gonorrhea excluding ophthalmia neonatorum	3	1	1	0	0	0	5
Gonorrheal ophthalmia neonatorum	18	4	22	3	0	2	49
Syphilis	313	150	149	78	31	9	730
	334	155	172	81	31	11	784

Table 7 presents the sex and race breakdown of these cases for each venereal disease. We perhaps should mention here that, although the standard classification of blind statistics has a separate category for congenital and acquired syphilis, we found that relatively few cases of syphilis were so classified and that the majority were classified as "syphilis—origin not specified." We have therefore combined congenital, acquired, and type not specified, and present them as total syphilis cases.

Regardless of race, the number of males whose syphilis resulted in blindness outnumbers the females two to one. It is believed that this apparent sex difference is due to the fact that the males, being the breadwinners, are likelier to apply for financial assistance, rather than any real difference in syphilis predisposing to blindness according to sex. It should be noted here that there is a difference of opinion expressed in the literature concerning the sex distribution for all causes of blindness. Marshall and Seiler[7] reporting a series of persons applying for pensions for the blind in certain areas in Scotland stated, "It is evident there is little difference in the incidence of blindness between the sexes, and the total number of males 2,015, and females 2,063, nearly conforms to the proportion of each sex in the population." They further state, however, that the etiological factors being separately considered, acquired syphilis causes more blindness in males than females, and that blindness due to congenital syphilis, on the other hand, is commoner among females than males. (It should be noted here that in the Ohio figures in which type of syphilis was specified males predominated more than two to one in both prenatal and acquired syphilis categories.) In direct contrast to the Scotland study, Sory and Caudill[8] in their article "The Cause and Distribution of Blindness in Kentucky Among Recipients of Aid to the Needy Blind" state that "males go blind almost twice as frequently as females."

According to the 1940 census, the ratio of whites to Negroes in Ohio was 19 to 1. All other things being equal, one would expect that the ratio of whites to Negroes blinded by syphilis in this study would be the same, 19 to 1. However, as table 7 indicates, the ratio of whites to Negroes blinded by syphilis is approximately two to one for both males and females. For an estimation of the number of white and Negro syphilitics in Ohio, selective service race specific seropositivity rates were applied to the Negro and white population totals based on the 1940 census. The resulting estimates were, of course, only approximate but serve our purpose here. We were interested to observe that in the syphilis prevalence estimates by race, calculated in this manner, white syphilitics outnumbered Negro syphilitics by about two to one. This same proportion, two to one, is evidenced in table 7, which shows the number of white syphilitics blinded by their disease as compared to the number of Negroes similarly affected. From these proportions and prevalence estimates, it would appear that race is not a factor in blindness as a complication of syphilis.

Age at loss of sight due to syphilis is presented by race and sex in table 8. It occurs to us that it may be well to stress again the fact that the examining ophthalmologists in our series did not routinely specify the type of syphilitic infection causing the blindness. In most cases the type of syphilis was called "syphilis—type not determined," and only a very small percentage was specified as congenital or acquired. For this reason the entire group is shown in table 8 as total syphilis without regard for type, and the 730 represent the entire series blinded by syphilis in the period under discussion. It may be logical to assume that the 30 cases under 2 years of age were caused by congenital syphilis. Furthermore a majority of the 58 cases between 2 and 20 years of age were no doubt also caused by congenital syphilis. On the other hand, it seems to us that most of those cases 20 years and over were probably caused by acquired syphilis, since congenital syphilis would, as a rule, have resulted in blindness before the patients reached the age of 20. One should note that 216 of the persons were of unknown age at time of loss of sight. Once again this lack of the age at which blindness occurred points to the fact that statistics of the blind are far from perfect and that examining physicians should attempt to determine and record better histories. From a review of the table in the earlier age groups in which congenital syphilis was most probably the factor, it would appear that there are two age ranges at which blindness is likelier to be manifested, one being the category under 2 years of age and the second period beginning at about 8 years of age.

[8] Sory, R., and Caudill, F. W.: The Causes and Distribution of Blindness in Kentucky Among Recipients of Aid to the Needy Blind, Kentucky M. J. **44**: 255 (Aug.) 1946.

Assuming that persons 20 and over were, by and large, blinded by acquired syphilis (and excluding those persons who lost their sight before the age of 20 and the unknown group), we calculated the median age at loss of sight for each race-sex group as well as for the total. These averages were as follows: white males 42.42 years, white females 45.25 years, Negro males 41.75 years, and Negro females 36.88 years. The total white and Negro median was 42.42 years.

In order to arrive at the time lapse for an infection of syphilis to progress to the complication of blindness, we computed the median age of infection of primary and secondary syphilis reported in Ohio from the annual reports of the Ohio Department of Health. Median ages in reported infections of primary and secondary syphilis in Ohio were as follows: white males 28.08 years, white females 24.57 years, Negro males 24.96 years, Negro females 23.50 years, with a total for all races and sexes of 25.04 years. In comparing the median age at loss of sight of persons blinded by syphilis with the median ages of reported primary and secondary syphilis infections in the state, we established an average time period of 17.38 years between the median age of infectious syphilis cases and the median age at which the loss of sight occurred. This difference suggests that an average of 17⅓ years is required for primary and secondary syphilis to progress to syphilitic blindness among infected persons fated to have the latter complication. The 17⅓ year differential is for all races and sexes and ranges from about 13 years among Negro females to almost 21 years among white females.

TABLE 8.—*Syphilis as a Cause of Legal Blindness in Ohio by Race, Sex, and Age at Loss of Sight, Before 1938 Through Dec. 31, 1948*

PRIMARY PATHOLOGICAL FACTORS

In addition to the previous information concerning the 730 persons blinded by syphilis, data were also tabulated on the primary pathological factors contributing to blindness as a result of syphilis. These data are presented in table 9.

Classified nomenclature of pathological factors by site and nature of affection as recommended by the Committee on Statistics of the Blind is used in the presentation of the information. Again it is well to point out that an adequate breakdown between congenital and acquired syphilis was unavailable in our series, and for this reason the 730 cases shown in table 9 include pathological conditions resulting from both congenital and acquired syphilis.

It will be noted that optic nerve atrophy is by far the greatest primary pathological factor in blindness due to syphilis. In our series, 494 cases (67.7%), or more than two-thirds of the total 730 cases, were made blind by optic nerve atrophy. It might be noted here that this percentage of optic nerve atrophy as the pathological factor among syphilitic blind has been reported by Klauder, Meyer, and Gross [9] to be 90%. The second specific pathological cause of blindness due to syphilis is interstitial keratitis, which was responsible for 76 cases, or 10.4% of the total 730 cases. In 38 additional persons, the pathological condition was located in the cornea (including ulcerative keratitis, keratitis not specified, ulceration and vascularization, and other affections of the cornea specified and unspecified). This brings the total number of cases whose pathological process was located in the cornea to 114, or 15.6% of the total.

---

[9] Klauder, J. V.; Meyer, G. P., and Gross, B. A.: Syphilitic Primary Atrophy as a Cause of Blindness: Importance of Early Diagnosis, Am. J. Syph. Gonor. & Ven. Dis. 32: 574 (Nov.) 1948.

It is probably reasonable to assume that most of the persons blinded by optic nerve atrophy were suffering from acquired syphilis and that the majority of the persons blinded by interstitial keratitis were victims of congenital syphilis.

Table 10 presents the topography of pathology by general anatomic site of the 730 cases in the series. Although almost 85% of the persons were blinded by pathology located in the optic nerve, visual pathway, cortical visual center, or the cornea, it is apparent that the disease is also capable of attacking and destroying the function of all other parts of the eye. The latter point indicates again that the physicians should consider all structures of the organ of vision when examining for manifestations of syphilis in the eye.

COMMENT

In analyzing the data concerning persons declared legally blind in Ohio, we were most impressed to learn that syphilis was first among the 10 specific causes, and that one out of every five blind persons in whom the etiological factor was known was blinded by syphilis. It is to be expected that a lag would exist between improved treatment methods and the appearance of a downward trend in the incidence of syphilitic blindness. However, it must be remembered that prior to the advent of the antibiotic era, syphilis was one of the few diseases for which specific therapy was available. This fact coupled with the availability of simple and reasonably accurate laboratory diagnostic aids and a wealth of clinical experience should have brought about a decreasing incidence of syphilitic blindness. The advent of penicillin therapy and intensive venereal disease control activities during recent years should be adding impetus to this decline. Syphilitic mortality, psychoses, and cardiovascular manifestations have been reported to be declining in incidence, yet it would appear that syphilis as a cause of blindness in Ohio has not perceptibly declined.

TABLE 10.—*Topography of Pathology in 730 Persons Blinded by Syphilis by General Classification*

Anatomic Site	No.	Percentage
Optic nerve, visual pathway and cortical visual center	502	68.8

Choroid and retina	59	8.1
Iris and ciliary body	21	2.9
Eyeball in general	19	2.6
Crystalline lens	13	1.8
Vitreous	2	0.3
	730	100.0

Our study suggests that an average 17 year period exists between initial infection and loss of sight, which would indicate sufficient time for the medical profession to diagnose and adequately treat these persons in order to prevent the appearance of this complication in a large percentage. This certainly presents a strong argument for intensive case-finding activity not only for the infectious stages of the disease, but also for those persons with hitherto unsuspected latent syphilis. The implied financial loss to both the person and the taxpayer who must support the afflicted is in itself another strong argument for intensification of syphilis case-finding and treatment activities by public health agencies, as well as by individual practicing physicians, in an application of the principles of preventive medicine.

Certainly there are few persons who do not consult physicians at least once in any given 17 year period of their lives. It is impossible to estimate how many of the 730 persons now blind because of syphilis would have normal vision today had their physicians maintained a high index of suspicion for the disease. Undergraduate and postgraduate medical training should be revised to include added emphasis on the diagnosis and treatment of syphilis.

Routine serologic tests assume added significance. These same 730 blind persons might have obtained an earlier diagnosis as a result of tests done for employment, hospital admission, or in accordance with premarital and prenatal laws. Premarital and prenatal examinations for syphilis have provided an effective screening process but are obviously not enough, for they are but isolated episodes in a person's life. Certainly detection of syphilis prior to the development of complications cannot be done by legislation but must be done by every practicing physician in rendering good medical care. Our study also reaffirms the findings of others that the lack of adequate recorded information seriously hampers efforts at analysis of the problem. We do feel, however, that certain valuable information is apparent.

The 7.9% of legal blindness in Ohio caused by syphilis represents a minimum figure, because many of the persons in whom cause was not specified or for whom the cause was attributed to "prenatal origin" undoubtedly were also blinded by syphilis. The figure quoted indicating that syphilis accounted for 20.9% of those persons in whom the cause of blindness was specified perhaps represents a more realistic estimate of the size of the problem.

The proportion of males to females, we believe, is of little importance as reported in the text, but the impression that race is not a predisposing factor to syphilitic blindness is valid from the evidence at hand. The preponderance of optic nerve atrophy and interstitial keratitis as pathological factors in blindness due to syphilis confirms findings reported previously in the literature.

SUMMARY

When the 6,442 persons declared legally blind during the 10 year period (Jan. 1, 1939 through Dec. 31, 1948) in whom the etiology of blindness was known were considered by general classification, infectious diseases ranked first among the general classes of causes of blindness. Among the 852 persons whose blindness was caused by infectious diseases, 507, or 59.5%, were blinded by syphilis.

Syphilis ranks first among all causes of blindness. The 507 persons blinded by syphilis represent 7.9% of all persons declared legally blind in Ohio during the 10 year period under consideration, including the large group of persons with blindness of undetermined or unspecified etiology. They, in addition, represent 20.9% of the total 2,427 legally blind among whom the etiology was determined, indicating that among those in

whom the etiological factors are known, one out of every five persons declared legally blind is blinded by syphilis.

When the percentage of persons declared legally blind because of syphilis is considered by year over the 10 year period of 1939 through 1948, no significant decrease in percentage is noted despite the fact that intensive venereal disease control activities were in effect in Ohio during the same years.

The percentage of blindness due to gonorrheal ophthalmia (0.4%) during the 10 year period under consideration is significantly lower than the percentage due to this cause (0.8%) in the several years prior to 1939.

Our study is compared in table 6 with seven other studies abstracted from the literature in order to present a composite picture of syphilis as a cause of economic blindness.

The study presents observations concerning age, sex, race, and pathological factors on 784 persons blinded by venereal disease among a total of 9,570 persons who have been declared legally blind in the state of Ohio and for whom records exist. Among persons blinded by syphilis considered in the study, males outnumber females by more than two to one. This apparent sex difference is more than likely due to the fact that the males, being the breadwinners, are more prone to apply for financial assistance rather than any difference in venereal disease predisposing to blindness according to sex. The ratio of whites to Negroes among persons blinded by syphilis considered in the study was approximately in proportion to the estimated prevalence of syphilis within each race group, which would suggest that race is not a factor in blindness as a complication of syphilis.

In a review of morbidity statistics for primary and secondary syphilis in Ohio, the median age was established at 25.04 years. Comparison of this figure with the median age at loss of sight (42.42 years) of presumably acquired syphilis cases considered in the study indicates that the infection requires an average period of time of 17.38 years to progress from the initial infection to loss of sight among those persons fated to be blinded by their disease.

The pathological factor in 67.7% of the persons blinded by syphilis was optic atrophy. Interstitial keratitis accounted for 10.4% of the total. Pathological factors in the remaining persons in the series were widely scattered as to topography and type of affection.

Throughout the study, obvious deficiencies in information were noted, indicating again that for purposes of analysis of the problem, accurate medical records must be maintained, including past medical histories and results of physical examinations, as well as accurate diagnoses.

405 Oak St.

FATAL INJURIES IN COMPETITIVE SPORTS

Thomas A. Gonzales, M.D., New York

The recent deaths of two professional boxers from injuries sustained in boxing bouts stimulated a survey of similar fatalities in this sport and in other athletic competitions. The purpose of the survey was to determine the type and frequency of the injuries and to correlate them with the particular kind of athletic activity. Accordingly, these deaths may best be considered under the following classifications: (1) sports characterized by body contact—football, wrestling, boxing, hockey and basketball; (2) sports in which missiles are thrown by the hand, driven by a bat or club or shot from weapons—baseball, cricket, golf, hockey and archery;[1] (3) sports in which falls or other miscellaneous accidents may occur—horse racing, polo, handball, basketball, and track and field events; (4) aquatic competition;[2] (5) sudden and unexpected natural deaths from existing acute, subacute or chronic disease precipitated by excitement, overexertion, exhaustion, or a combination of these factors.

In New York City in the 32-yr. period from 1918 to 1950, inclusive, fatal injuries were distributed in the various sports, as seen in the table.

SPORTS CHARACTERIZED BY BODY CONTACT

Football.—Most of the injuries in football were from direct violence in line play, in blocking and in tackling. Only on a few occasions was indirect force a factor, notably in cervical spine injuries. Other sources of direct and indirect trauma were kicks, falls, trampling, torsion and crushing force. In some cases, the manner of injury was unknown.

An acute, subacute or chronic focal infection followed by some form of generalized sepsis was a frequent cause of death in football injuries. Of ten such cases, the lower extremities were involved in five and the pelvic region in three, and there were two cases of head injuries. In this group, three instances of acute osteomyelitis were observed; one of the players developed a severe blood stream invasion and expired on the eighth day after the

Fatalities

Sport	Number of Cases	Necropsies
Football	22	12
Soccer	2	2
	21	21
	2	2
Baseball	43	27
Cricket	1	1
Golf	1	1
Basketball	7	4
Handball	3	2
Polo	1	0
Relay races	1	1
Total	104	73

From the Office of the Chief Medical Examiner.

[1] Deaths in hunting accidents and in other noncompetitive activities, such as bathing, boating and fishing were not considered; nor were the sudden and unexpected deaths, unless they were associated with injuries.

[2] Fatalities in hockey, aquatic competition, horse racing and archery were not observed.

injury. The primary focus demonstrated by operation was situated in the right iliac crest. In another case, a septicopyemia followed an acute osteomyelitis of the ankle, and the third developed a staphylococcic septicemia from an acute process in the right tibia. The clinical diagnoses in these cases were confirmed by operation and by necropsy.

In addition to the acute cases, there were four instances of chronic osteomyelitis that were attributed to football injuries. In one case, the necropsy revealed a low grade staphylococcic sepsis that followed a chronic suppurative and necrotizing lesion in the right iliac bone with extension to the soft parts of the iliac fossa, to the buttock and to the adjacent hip joint, where a suppurative arthritis was found. A second patient died of postoperative shock after a sequestrotomy for a chronic osteomyelitis of the femur, and a third expired of chronic sepsis also from a primary lesion in the femur. One instance of chronic osteomyelitis of the lumbar vertebras with suppurating osteoarthritis of the sacroiliac joint was encountered. This player was alleged to have received an injury to the lumbar region in a game 10 yr. prior to his death.

Both of the players in this group who had head traumas sustained injuries that resulted in infected hematomas of the scalp from which cellulitis and sepsis developed.

Intracranial injuries with hemorrhage and cerebral compression were observed on four occasions. There were three deaths from subdural hemorrhage without fracture,[3] two of which were of the acute variety in that compression symptoms developed shortly after the trauma. The other case presented the characteristics of a secondary or slow hemorrhage. The player was kicked in the head and complained of intermittent headaches but otherwise appeared in good condition. Two weeks later he began to exhibit signs of compression with headache, dizziness, occasional vomiting, hemiparesis, and stupor deepening into coma. A large subdural hemorrhage with the indications of increased cerebral pressure was found at the autopsy. In the remaining case of this series, there was a fracture of the skull with an epidural hemorrhage, which was sustained when the player ran into a wall on one side of the playing field.

Three deaths were the result of spinal injuries. There were two patients with fracture-dislocation, one involving the fourth and the other the fifth cervical segments of the spinal cord, with crushing injuries to the cord and complete motor and sensory paralysis below the level of the cord lesions, and the third had a fracture in the thoracic region, with a long-standing transverse myelitis and a urinary tract infection. The manner of injury in these cases was unknown. Such injuries are usually caused by indirect trauma from hyperextension of the neck or a twisting force applied to the head.

Intra-abdominal injuries were responsible for four deaths, and hemorrhage into the abdominal cavity was found at the necropsies on three occasions. One of these followed a rupture of the spleen from a blow on the abdomen, another presented several lacerations at the roots of the mesenteries of the small and large intestines with about 8 oz. (250 cc.) of free blood in the abdomen and an extensive retroperitoneal hematoma; the third patient had a rupture of the jejunum and the adjacent mesentery with intra-abdominal hemorrhage. The latter two were kicked in the abdomen. An acute suppurative peritonitis and septic pneumonia following a rupture of the ileum was responsible for the fourth death in this series and the patient received his injury in some unknown manner.

There was one instance of tetanus that followed a compound fracture of the right middle finger.

Injuries in soccer football were held responsible for two deaths; both players collapsed on the field. One of them had a fracture of the skull and an epidural hemorrhage and the other, alleged to have received an injury to the abdomen, showed no evidence of trauma. The necropsy established the cause of death as a luetic aortitis with stenosis of the ostia of the coronary arteries.

Boxing.—Injuries in boxing were usually the result of blows on the head or were sustained in a knockdown when the head of the boxer came in contact with the ring floor.

Of the 21 deaths in this sport, 15 were caused by subdural hemorrhage. Of these, 13 were attributed to ruptures of cortical cerebral blood vessels,[4] one to hemorrhage from a superficial cortical brain laceration, and another to a questionable injury of the posterior cerebral artery. Eight hemorrhages involved the left side and five the right, and two were bilateral. The amount of blood found in the subdural space varied from 2 to 8 oz. (60 to 250 cc.) or more. Ten of the 15 patients died within 40 hr., the period varying from one-half hour in one of the bilateral hemorrhage cases, to 38 hr. The other patient with bilateral hemorrhage survived for five and one-half hours. The remaining five patients expired after two days (in 2 cases), three days, one week and about two weeks, respectively. The latter boxer was knocked unconscious twice in a period of two weeks and apparently suffered no ill effects from the last episode. A few days later, he developed symptoms of cerebral compression and entered the hospital in an unconscious state with fixed dilated pupils, increased patellar reflexes, ankle clonus, equivocal Babinski sign, absent adbominal and cremasteric reflexes and a spasticity of the left arm. At the autopsy about 6 oz. (180 cc.) of dark red fluid blood was found under the left dura and there was marked flattening of the right cortical convolutions. Partly covering the inner surface of the dura on the left side was a brownish membrane that could be easily stripped off. Also on this side a cystlike cavity was found situated in the frontoparietal region. It measured 2½ by 4 in. (5.4 by 10.2 cm.), was covered by a delicate friable membrane and contained bloodstained fluid. The depressed base of the cyst in the frontoparietal lobes was covered by intact arachnoid membrane. In addition, the posterior border of the greater wing of the sphenoid on the left side, was rounded and thickened in comparison with the sharp-edged wing on the opposite side and the middle fossa of the skull on the left was wide and deep. A knoblike exostosis, remotely situated from the cyst and measuring ½ in. (1.3 cm.) in diameter, projected from the upper surface of the left petrous temporal bone.

[3] Hey: Subdurales Hämatomals Sportverletzung, Deutsche Ztschr. ges. gerichtl. Med. 5: 12-16, 1925.

[4] Vance, B. M.: Ruptures of Surface Blood Vessels on Cerebral Hemispheres as Cause of Subdural Hemorrhage, Arch. Surg. 61: 992-1006 (Dec.) 1950.

The position of the cystlike cavity in the subdural space and the character of the covering membrane appear to exclude porencephaly. The possibility of an old localized and encysted subdural hemorrhage was considered.

Surface injuries were noted at the autopsies of eight patients. They varied from contusions and abrasions of the forehead, eyelids, nose, lips, cheeks and ears to a ½ in. (1.3 cm.) laceration on the chin in one boxer. The remaining seven patients did not show any of these lesions. The more pronounced lacerations that induce boxing officials to terminate bouts were not observed.

Some of the patients with subdural hemorrhage exhibited other brain lesions. There were a few scattered pinhead-sized hemorrhages in the white matter of the parietal lobe in one patient, a few petechial hemorrhages in the pontile peduncle in another, very slight localized effusions of blood under the cortical arachnoid membrane in two others, and a fifth patient presented a few small hemorrhages in the lenticular nucleus. For the concepts of the production and the remote effects of these hemorrhages, the reader is referred to Leary,[5] Cassassa[6] and Martland.[7] In addition to these lesions, several patients showed streaklike hemorrhages in the pons, which were considered due to pressure effects.[8]

Ruptures of the cortical "bridging veins" were responsible for most of the subdural hemorrhages in this series.[9] Tears of the cortical arterioles have also been described by various investigators,[10] and others have advanced the theory that these ruptures were the result of anteroposterior force and oscillation of the brain,[11] or in arteries, of a sudden release of pressure after flattening of the brain against the calvarium followed by arteriolar engorgement and rupture.[12]

Various grades of hypostatic pneumonia complicated some of the delayed deaths from subdural hemorrhage.

The lesions found in the other boxers varied considerably. One heavyweight fighter suddenly collapsed in a late round of a bout and died after three days. The necropsy disclosed pinhead-sized hemorrhages in the white matter of the basal ganglions, thrombosis of a small cortical vessel situated at the junction of the temporal and occipital lobes and a wedge-shaped area of softening under the thrombosed vessel, which was interpreted as an infarct. Microscopic examination confirmed the gross findings, and, in addition, some of the small blood vessels in the white matter adjacent to the infarct showed a perivascular round-cell infiltration, and a similar infiltration was found in the meninges. Another boxer, having been knocked down, his head striking the ring floor, showed small scattered hemorrhages in the optic thalamus, the cerebellum, and the region of the fourth ventricle. He survived four hours.

Injuries of the abdominal organs are uncommon in boxers. Only one case of suppurative peritonitis from a rupture of the small intestine was encountered. The victim died six days after receiving a blow on the abdomen. Similarly, with the exception of fractures of the ribs that occur occasionally, injuries to the chest organs are very rare. They were not observed in this study.

Occasionally, the autopsy fails to demonstrate evidences of trauma in boxers who die in the ring or shortly after a bout. Such was the case in two boxers, one of whom collapsed and died in the ring, and the only lesions found were cardiac dilatation and hypertrophy. The other boxer was admitted to the hospital in an unconscious state with indefinite symptoms of cerebral compression, and the autopsy likewise failed to disclose trauma. The death was attributed to cerebral concussion. A third death from status epilepticus was also observed, in which repeated beatings in the prize ring eight years prior to the onset of the convulsive seizures, was held to be the cause.

Wrestling.—Two deaths due to wrestling were noted, one from abdominal hemorrhage and a rupture of the spleen and the other from an acute lobar pneumonia complicating a fracture of the thoracic part of the spine. In both cases, the manner of injury was unknown. The first patient survived two days and 11 hr. and the second, 11 days.

DEATHS CAUSED BY MISSILES

Baseball.—Most of the injured in baseball were amateurs or semiprofessionals. Only one major league player was fatally injured when he was struck on the head by a pitched ball. In most instances, the injury was caused by a blow from a baseball that had been thrown, or driven by a bat. A few were injured in collisions between players, in falls or when sliding into a base. Head injuries predominated, notably fractures of the skull, of which there were 25 cases. Fourteen of these were accompanied by epidural hemorrhage and two of the 14 epidural cases were complicated by direct and contrecoup lacerations of the brain with subdural and subarachnoid hemorrhage. Four others of this group showed associated brain trauma in the form of slight to moderate contusions and lacerations that were thought to be of insufficient severity to influence the diagnosis of cerebral compression from epidural hemorrhage. The characteristic localized depression in the cerebral cortex under the epidural lesion was present in all of the 14 cases.

There were 11 cases in which diagnosis was subdural or intermeningeal hemorrhage associated with fractures; seven of these were confirmed by necropsy and one by operation. Included in this group was one case of fracture with bilateral tentorial tears, subdural hemorrhage and petechial hemorrhages in the brain substance. The player with the latter condition suffered an injury to the head by a baseball and succumbed one-half hour after the accident.

Two instances of subdural hemorrhage without fracture were observed. One of these players was struck on the head by a baseball four days before entering the hospital. On admission he was unconscious and had a dilated right pupil and indefinite neurological signs. The necropsy disclosed more than 8 oz. (250 cc.) of fluid and clotted blood in the right subdural space, with marked flattening of the left cortical convolutions. When the brain was incised, a small amount of clotted blood was evacuated from the left temporal lobe. This lesion was interpreted as a subcortical laceration. The other player was struck by a batted ball and sustained a subdural hemorrhage, presumably from a rupture of a cortical blood vessel.

The death that occurred in a softball game was attributed to a subarachnoid hemorrhage and a fracture of the mandible. The player was injured when a bat that accidentally slipped from the hands of another player struck him on the side of the head. Aneurism of the cerebral vessels was not found.

An unusual case of traumatic hematoma of the head of the pancreas was disclosed at an autopsy. The injury was received in a collision with a player in an attempt to catch a fly ball. In addition to the hematoma, there was an extravasation of blood in the wall of the duodenum and an extensive fat necrosis. The patient entered the hospital in severe shock but survived seven days. The question of a coincidental spontaneous hemorrhage in the pancreas must be considered in such cases.

Infectious processes were responsible for 13 deaths in this game. There were six cases of osteomyelitis, five of which were acute and one chronic. The lower extremities were involved in all but one case. In the latter there were suppurative and necrotizing foci in the bodies of the ninth and 10th thoracic vertebras which followed an injury to this region by a baseball. The necropsy disclosed, besides the local lesions, thrombosis of the surrounding veins and septic infarcts of the lungs complicated by an empyema. In one of the acute cases there was a long-standing chronic osteomyelitis of the left femur, which was apparently quiescent. After an injury to the left knee by a batted ball, an acute process developed at the site of the old disease.

Acute suppurative peritonitis was the cause of death in three cases. In two of these, exploratory laparotomies revealed ruptures of the ileum. One of the players was struck on the abdomen with a bat and the other was accidentally kicked in the same region. The third player, struck by a batted ball, suffered no ill effects for five days, after which he complained of abdominal pain, with vomiting and constipation followed by meteorism and singultus. At the autopsy, a suppurative peritonitis and a perforation of the jejunum surrounded by a contused area were found. This lesion was interpreted as an original contusion, which became devitalized in the intervening five-day period and finally ruptured.

Three cases of generalized blood stream infection were attributed to baseball injuries. One was septicemia, due to a hemolytic Streptococcus following an injury to the thumb, another a staphylococcic sepsis from an infected finger and a third, a laceration of the scalp complicated by a cellulitis and a blood-stream invasion. In one instance of sudden death from a massive pulmonary embolism, thrombosis of the femoral vein and a fracture of the femur were observed, and, in another patient, a player who was struck on the chest by a batted ball and who immediately collapsed and died on the playing field, a dilated and hypertrophied heart was the only lesion found at the necropsy.

Two other deaths followed injuries by missiles. One occurred when a cricket player was struck in the abdomen by a cricket ball driven by a bat and sustained a rupture of the small intestine with acute peritonitis and the other, a caddy, died of a fractured skull and intracranial injuries when a golf ball struck him on the head.

Basketball.—Seven deaths occurred in basketball. Most of them were due to infections from relatively trivial injuries, such as a staphylococcic septicemia from an infected contusion of the thigh, a septicemia and an osteomyelitis of the femur, a similar condition with the primary lesion in the tibia, a sepsis and suppurative pericarditis following a contusion of the hip, and a post-traumatic anemia from persistent nasal hemorrhage with infection and ulceration of the nasal mucosa, which followed mild trauma to the face.

Of the two remaining patients in this category, one died of subdural hemorrhage following head trauma and the other expired from an alleged post-traumatic epilepsy supposedly due to a head injury a year prior to the fatal outcome.

Handball.—There were three deaths in this sport. Two were caused by fractures of the skull and epidural hemorrhage, one of which was subjected to necropsy and the other to operation. The third patient died of an acute leptomeningitis following a laceration of the brain without fracture. In the latter case, according to the history, the injury was sustained when a handball struck the player on the head.

A fracture of the cervical part of the spine was the cause of death of a polo player who fell from his horse, and a relay runner expired from an acute suppurative peritonitis, the consequence of a rupture of the large intestine, when he ran into railing along the side of the track.

COMMENT

The literature of the past 30 yr. contains a fair number of references to nonfatal injuries in the various branches of athletics, but fatal trauma has received scant attention, with the notable exception of the deaths in boxing. Most of the contributions in the other sports refer to isolated instances of deaths in which the circumstances are purely accidental, whereas in boxing the suspicion of a willful attempt to seriously injure an opponent may instigate a judicial inquiry, hence the medicolegal implications of such deaths have stimulated more thorough medical investigations.

A number of investigators have contributed to the study of nonfatal and fatal injuries in boxing,[13] and some of them have also considered the mechanisms of the "knockout" and their relation to the sudden deaths in the sport. Wolff,[13a] in a general review of boxing injuries, collected histories of 12 fatalities of which six were caused by subdural hemorrhage, two by fractures of the skull and one each by shock, brain hemorrhage, rupture of the intestine, and edema of the glottis. The latter death, reported by von Sury,[14] followed a blow on the side of the neck, which caused hemorrhage in the laryngneal region, glottic and pulmonary edema, and death shortly after the injury was received. Lami,[13c] Jankovich,[13b] and Wolff [13a] paid particular attention to the phenomena of "knockouts" and to the causes of sudden death in boxing, while other observers discussed the lesions found at the necropsies on boxers' deaths.[13d,e]

It is generally conceded that the three kinds of trauma most likely to cause unconsciousness are blows on the chin, injury to the abdomen, and trauma to the carotid sinus. Most observers believe that sudden force applied to the chin causes cerebral concussion, reflex action on the labyrinth, and a Ménièrelike syndrome; an injury to the abdomen affects the vagus terminals and causes vasodilatation in the splanchnic area, interference with heart action and pulmonary circulation, and dyspnea. The sequence of events of trauma to the carotid sinus that was experimentally demonstrated by Hering,[15] in 1927, is regarded as a reflex ventricular fibrillation, dilatation of the blood vessels about the sinus, and a cerebral anemia. The relation of these phenomena to unexplained sudden deaths in boxers with negative necropsy findings is accepted by most investigators.

The late neurological manifestations in retired pugilists, first described by Martland [7] under the title of "Punch Drunk" and supposedly caused by repeated traumas to the head during their ring careers, stimulated the interest of a number of investigators who studied the various mental and neurological disturbances in these cases.[16] For further information on the subject, the reader is referred to their contributions.

Among those who have contributed to the subject of nonfatal injuries in football were Hanson and Hauser [17] and McPhee,[18] in their studies of the lesions among college players, and Burnett [19] and Horan,[20] who considered them among high school students. No serious craniocerebral, intra-abdominal or chest injuries were observed by these authors. Most of the injuries involved the extremities in the form of sprains, muscle and tendon ruptures, fractures, and dislocations. McPhee collected information on 889 injuries in 563 cases over a period of 10 yr. and found four fractures of the transverse processes of the lumbar vertebras, with three uneventful recoveries. In the remaining case troublesome eye symptoms developed, whose relation to the injury was questionable. The most serious injuries found in these studies were a backward dislocation of the leg at the knee with avulsion of the soft tissues and a subsequent thrombosis that necessitated amputation, two fractures of the spine, and injury to the kidney followed by hematuria. All the victims apparently recovered. Other contributors to studies of nonfatal injuries in this game were Tillman [21] and Blondal [22] and case reports of fatal traumas were published by Séjournet,[23] Frank,[24] Lande and his associates,[25] and others.

In other sports, no recorded death was found in the literature of the past 10 yr. with the exception of a case reported by Guimbellot and his co-authors [26] who reviewed the clinical observations and the autopsy findings in a case of fatal fracture of the cervical part of the spine with injury to the cord, incurred in a wrestling match. Most of the injuries were mild in nature and were troublesome mainly from the standpoint of time loss in participation in the sport.[27] On a few occasions, severe injuries with lasting effects compelled the cessation of all athletic activities.

CONCLUSIONS

It is evident that the method of play in games and the kind of athletic activity in the other competitions exerts an influence on the type of injury most likely to occur in a particular sport. Thus, subdural hemorrhage is frequent in boxing, whereas fractures of the skull and intracranial injuries predominate in baseball. Deaths from the immediate effects of trauma, such as hemorrhage and shock, and from infection were about equal in football, and infections appeared to prevail in basketball. Many of these infections followed relatively trivial injuries that would have possessed little significance had infection not set in. Since the introduction of the sulfonamides and the antibiotics, a marked reduction in the incidence of these infections has been apparent; so today they are rarely seen at the necropsies on fatal cases. Incidentally, the efforts to reduce the incidence of nonfatal accidents in the various branches of athletics by revision of the rules, by better medical supervision and coaching, and by the introduction of protective equipment have met with some measure of success.

In recent years, opponents of boxing have expressed the opinion that the sport should be abolished, that it is potentially dangerous and not necessary to the development of those attributes which are most desirable in young men. Thirty-two years of boxing competitions, however, have produced fewer deaths, in proportion to the number of participants, than occur in baseball or football and far fewer deaths than result from daily accidents. It seems that the moral and physical benefits derived from boxing far outweigh the dangers inherent in it or any of the other competitive sports.

CLINICAL NOTES

ASCITES DUE TO MYXEDEMA

REPORT OF A CASE

Martin L. Tracey, M.D.
and
Edward J. Donovan, M.D., Boston

Of the many causes of recurring ascites in patients who do not have evidence of the more common causative factors, such as cardiac, renal, or hepatic disease, myxedema is rarely considered and rarely encountered. Because of the comparative rarity of this condition the following case is reported.

REPORT OF CASE

A 45-yr.-old woman was first seen at the clinic on Nov. 1, 1949, with the chief complaints of swelling of the abdomen, weight loss, and weakness of 10 weeks' duration. She had had a thyroidectomy in 1940 for hyperthyroidism; this operation was followed by myxedema. At that time she was advised to take 1½ grains (0.10 gm.) of thyroid daily for the rest of her life. She had taken this dosage until about nine months before her present admission when an examination by her local physician revealed a basal metabolic rate of — 3. The thyroid medication was decreased to one or two ½-grain (30 mg.) tablets weekly. She had remained in fairly good health until 10 weeks before coming to the clinic, at which time total hysterectomy and bilateral salpingo-oophorectomy were performed because of a long period of menorrhagia. At the time of operation there was no evidence of malignant disease in the pelvis. About one week after the operation she noted swelling of the abdomen and considerable weakness. The abdominal swelling had increased to such an extent that it necessitated two abdominal taps in the 10-week interval; each yielded about 8 l. of yellow fluid. There was no history of abdominal pain, nausea or vomiting, and she stated that her appetite was excellent. After operation she had had three or four bowel movements daily.

The patient was admitted to the hospital on Nov. 3, 1949, for further study and observation. Physical examination on admission revealed that she was pale, the hair was coarse and dry, the skin was dry with loss of turgor, the eyebrows were sparse, and she had ascites. The heart and lungs were normal and the blood pressure was 152 mm. systolic and 100 mm. diastolic. There were no palpable lymph nodes and no palpable organs or masses in the abdomen.

Laboratory studies demonstrated a hemoglobin content of 13.5 gm., a leukocyte count of 6,700, and a normal differential count. The nonprotein nitrogen was 31 mg. per 100 cc., serum chloride 99 mEq., serum bilirubin 0.2 mg. per 100 cc., blood cholesterol 142 mg. per 100 cc., and a total serum protein of 4.9 gm., with an albumin level of 2.9 gm. and globulin level of 2 gm. Liver function tests otherwise were within normal limits. Test of the stools with guaiac gave negative results. The specific gravity of the urine was 1.018, and there was a trace of albumin; microscopic examination of the urine gave negative results. Roentgenograms of the gastrointestinal tract made after paracentesis demonstrated some forward displacement of the stomach in the region of the antrum. A roentgenogram of the chest revealed elevation of both diaphragms.

Abdominal paracentesis was performed and more than 11 l. of murky yellowish fluid having the characteristics of a transudate was obtained. Some of this fluid was injected into a guinea pig and some was centrifuged; sections made of the sediment were negative for tumor cells, as was the guinea pig injection. After the abdominal tap, examination of the abdomen revealed no palpable organs or masses.

The question then arose as to whether or not the ascites was the result of myxedema. Since the ascites had begun one week after the pelvic operation, and the patient had been taking one or two ½-grain (30 mg.) tablets of thyroid per week until two weeks before entry and was gaining 2 lb. (0.75 kg.) in weight per day, surgical exploration of the abdomen was decided upon.

Operation was performed on Nov. 17, 1949. No definite cause of ascites was found. The portal pressure was recorded as 90 mm. of water. Biopsy specimens of the liver, head of the pancreas, and enlarged nodes of the small bowel were reported as negative. The peritoneum was somewhat reddened and inflamed, but no definite evidence of tuberculosis could be seen. Specimens of the abdominal fluid were taken for smear, culture, and guinea pig injection, all of which subsequently proved negative for acid-fast organisms. With the clinical evidence of myxedema and the negative exploratory operation it was thought that the ascites was most likely the result of the poorly treated myxedema, and administration of thyroid, 2 grains (0.12 gm.) daily, was begun. In addition, the patient was given intravenous injections of 25 gm. of serum albumin daily, which raised the total protein to 6.5 gm., with an albumin content of 4.5 gm. and a globulin content of 2 gm. The ascites rapidly subsided, and her mental and physical appearance improved noticeably. She was discharged from the hospital on the 16th postoperative day with instructions to continue the daily dosage of 2 grains (0.12 gm.) of thyroid for two months and then to have a recheck examination and further evaluation of her dosage requirements. In a letter dated May 13, 1950, the patient stated that she had been taking thyroid as instructed and had not returned for check-up examination because she "had not felt so well in the past 15 years and did not want to be reminded of doctors." There had been no recurrence of ascites during this interval.

COMMENT

Ascites occurring as a direct result of myxedema has only occasionally been mentioned in medical literature. The earliest reference to its occurrence appears to be that of Kocher,[1] who, in 1883, reported two cases after total thyroidectomy. Faber,[2] in 1919, also reported the occurrence of myxedema after thyroidectomy in one case. Most of the references to the subject appear in the older literature, although one of the recent standard works on the subject noted its occurrence.[3]

The mechanism of production of ascites in these cases is not known, but it apparently involves all the serous surfaces, as cases have been reported associated with pericardial and pleural effusions either alone or in conjunction with fluid collections elsewhere in the body.[4] The problem of fluid in the various serous cavities raises two questions: 1. Has the myxedema caused myxedema heart disease and, as a result, congestive failure with ascites the symptom? 2. Is ascites caused directly by myxedema in the same manner as is subcutaneous edema, which is seen in this disease?[4,5]

It is doubtful that congestive failure is part of the picture of true myxedema heart. In Zondek's original de-

[3] Means, J. H.: The Thyroid and Its Diseases, ed. 2, Philadelphia, J. B. Lippincott Company, 1948, chap. 9, pp. 211-212.

scription of myxedema heart, there was no definite evidence of congestive failure, and no mention was made of fluid in the abdominal or pleural cavities [5] in the seven cases he reported. This also appears to have been true in several cases reported by others, including Faber,[2] Mussio Fournier,[4a] Marsh, [4b] Evans,[4d] and Hatlehol.[6]

Willius and Haines,[7] in a study of 162 cases of myxedema heart, found only one patient with signs of definite congestive failure, and this patient had advanced cardiovascular renal disease. In Christian's series of 32 cases none showed evidence of congestive failure or ascites.[8] Fahr,[9] on the other hand, reported that 75% of his patients with myxedema showed some manifestations of heart failure and 30% of all his patients with myxedema had shown very severe symptoms and signs of heart failure that were promptly relieved by administration of thyroid. In support of his view he referred to the experimental work of Goldberg,[10] who removed the thyroids of sheep and goats immediately after birth and examined these cretin animals at necropsy one to two years later. Pronounced arteriosclerosis was found, in addition to generalized anasarca and stasis of liver, kidneys, and lungs. In nearly all the animals the heart was described as dilated, flabby, and pale. Hanssen,[4g] however, believed that the pronounced arteriosclerosis present in these cases after removal of the thyroid was the cause of cardiac insufficiency. He thought that the experimental observations were in accord with clinical experience that myxedema causes early and widespread arteriosclerosis that does not diminish after thyroid therapy. This was also the opinion of Christian,[11] who stated that "the myocardial disturbances caused by thyroid deficiency and cured by thyroid feeding are relatively rare, while arteriosclerosis and coronary disease coincident with thyroid deficiency are much more common."

Mussio Fournier [4a] stated that the action of thyroid extract on dropsy syndromes developing independently of thyroid insufficiency was undeniable but inconstant and that it rapidly lost its power; but, when thyroid extract was administered to a patient with a dropsy syndrome that had developed on a myxedematous basis, the action of the drug was constant and lasting. This appears to be borne out in the cases reported by Hanssen, in which ascites recurred and disappeared as thyroid was stopped or administered. When thyroid was given continuously, ascites permanently disappeared. This also appears to be true in the case here reported, as ascites did not recur after thyroid in proper dosage was begun until the patient herself decreased this dosage some seven months before she came to the clinic. It must be concluded that the true thyroid heart is a rare phenomenon and that, when present, it is rarely associated with congestive failure.

The cardiac output in cases of myxedema heart has been studied and found to be diminished [12] but without increase in the venous pressure.[13] In the case reported by Evans [4d] a series of venous pressures was determined for over a month; the pressures remained at a constant level in spite of administration of digitalis. Blumgart [14] also described normal venous pressures in seven myxedematous patients in whom there were no signs of congestive failure. Capillary filtration may be decreased [15] and the capillaries constricted.[16] The osmotic pressure of the blood [17] and the albumin content of the blood serum [18] tend to be increased. Careful observations of the type of ascitic fluid found in myxedematous ascites show nothing to distinguish it from ascites resulting from other causes.[19] A high protein content was reported in one case but not in the cases reported by others, including Faber [2] and Hanssen.[4g] It has been shown that a high protein level, as was found in this case, is not unusual in fluid of this density, namely 1.020.[20] The amount of ascitic fluid that may be found in these cases is sometimes surprising. In Hanssen's case,[4g] over an eight-year period before the diagnosis was finally established, the patient had a total of 157 paracenteses, yielding 1,357 l. of ascitic fluid, and in a case recently reported by Paddock [20] a single abdominal tap yielding 8 gal. (30 l.) of ascitic fluid.

SUMMARY

A case of ascites resulting from myxedema has been presented. It is of interest that the ascites followed a pelvic operation by one week. With the administration of thyroid, the patient has shown improvement, clinically, and the ascites has not recurred over a period of six months.

605 Commonwealth Avenue.

COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION

The Council on Physical Medicine and Rehabilitation has authorized publication of the following reports.

Ralph E. DeForest, M.D., *Secretary.*

HELIO-THERM, MODEL F, ACCEPTED

Manufacturer: Ultrad Laboratories, 208 Maplewood St., Watertown 72, Mass.

The Helio-Therm, Model F, is a generator of radiations including the near ultraviolet, the visible and the near infrared wavelengths. The radiation comes from an incandescent tungsten filament 300-watt lamp. The lamp (bulb) operates at a voltage higher than its rated voltage. The tungsten is "superheated" by electric current passing through the filament, giving a temperature which is stated by the firm to be approximately 3,200° Kelvin. The inside of the lamp is partly coated with aluminum to make a reflector and the emerging beam is passed through 5 cm. (2 in.) of glycerin. This filtration is intended to remove the longer infrared wavelengths. Because of the "superheating" the life of the lamp is shortened to an average of about 25 hours, according to the manufacturer. The incandescent tungsten lamp burning at a higher voltage produces an increased amount of radiation throughout the whole spectrum.

The Helio-Therm, Model F, is a floor lamp standing on a four-legged castered base. A horizontal arm, which can be raised or lowered, bears the generator. The latter is shaped like a large automobile headlight, and can be aimed in various directions. Unpacked, the device measures 162 by 65 by 72 cm. (65 by 26 by 29 in.) and weighs 13.1 kg. (29 lb.). Crated for shipment it measures 60 by 45 by 60 cm. (24 by 18 by 18 in.) and weighs 18 kg. (40 lb.). The foreign shipping weight is 40 kg. These shipping weights include the chrome tube stand (5 ft. in length, separately packed) and an extra bulb. The device will operate on either direct current or alternating current of any usual frequency, and it draws 300 watts.

In a laboratory acceptable to the Council, the spectral distribution of the energy from the lamp was examined both with and without the glycerin filter by means of a quartz spectrometer. It was found that the band spectrum extends from about 3,100 angstroms to about 14,000 angstroms without the glycerin filter and to about 11,000 with the glycerin filter.

The manufacturer submitted data showing that of the total radiant energy emitted by the Helio-Therm, Model F, in the spectrum bounded by 3,100 angstroms on the ultraviolet side and 14,000 angstroms on the infrared, approximately 2% of the total energy is in the near ultraviolet zone (3,100 to 3,900 angstroms), roughly 37% is in the visible zone (3,900 to 7,600 angstroms) and 61% in the near infrared zone (7,600 to 14,000 angstroms) which has been filtered out by the glycerin cell. The total intensity at 2 in. treatment distance is 3.2 gram calories per square centimeter per minute, or approximately three times the intensity of sunlight.

Exploratory measurements of the radiation energies were made for given distances, from which it appears that for short distances (5 cm. to 15 cm.) the radiation intensity per square centimeter from the Helio-Therm, Model F, is at least equal to that of sunlight measured under similar conditions.

While the apparatus is acceptable as a source of radiant heat for local application, the Council was not convinced that this "superheated" tungsten lamp is more efficacious therapeutically than a similar high powered (500 or 1000 watt) tungsten filament incandescent lamp operating at rated voltage, with a filter, at a treatment distance, namely, that distance between the lamp and the patient at which one approaches the threshold of pain due to excess temperature rise in the skin and blood stream.

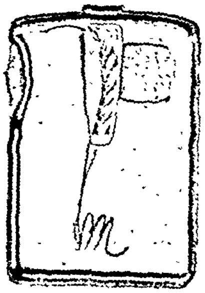
Although, in the opinion of the Council on Physical Medicine and Rehabilitation the firm has not produced critical evidence that the radiation from a "superheated" tungsten filament lamp has superior therapeutic qualities, the Council voted to include the Helio-Therm, Model F, in its list of accepted devices as a local applicator of radiant heat.

MICROTONE HEARING AID, MODEL T-10, ACCEPTED

Manufacturer: The Microtone Company, Ford Parkway on the Mississippi, St. Paul 1.

The Microtone Hearing Aid, Model T-10, is a hearing aid of conventional design, one distinctive feature being the absence of a tone-control. The wheel-type control is for Off, On, and Gain. Excluding the latch on top and the clothing clip on the front it measures 63 by 44 by 21 mm. The transmitter alone weighs 70 gm. With the batteries it weighs 101 gm., and the receiver and cord add 12 gm.

From acceptable sources the Council obtained evidence that the instrument was of good construction, performed as represented by the manufacturer, and satisfied the published minimum requirements of the Council for acceptable hearing aids. The Council on Physical Medicine and Rehabilitation voted to include the Microtone Hearing Aid, Model T-10, in its list of accepted devices.

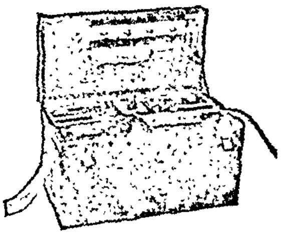


Microtone Hearing Aid, Model T-10

EDIN ELECTROCARDIOGRAPH, MODEL 220, ACCEPTED

Manufacturer: Edin Company, Inc., 207 Main St., Worcester 8, Mass.

The Edin Electrocardiograph, Model 220, is a direct writing instrument. The acceptance of a previous Model 210T, which likewise produces pen-and-ink records on permanent graph paper and has the same power consumption, was announced in The Journal of May 14, 1949. The present Model 220 weighs 13 kg. (29¾ lb.) and measures 25 by 21 by 43 cm. (10 by 8⅜ by 17 in.). When packed for domestic shipment it weighs 16 kg. (35 lb.) and measures 34 by 38 by 49 cm. (13½ by 11¼ by 19½ in.). The foreign shipping weight is 27 kg. (60 lb.). Included in these shipping weights are accessories.



Edin Electrocardiograph, Model 220

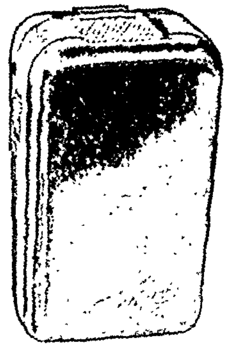
Evidence that the apparatus was sound in construction and satisfactory for its purpose was obtained from laboratories and clinics acceptable to the Council. The Council on Physical Medicine and Rehabilitation voted to include the Edin Electrocardiograph, Model 220, in its list of accepted devices.

MAICO HEARING AID, MODEL J, ACCEPTED

Manufacturer: The Maico Company, Inc., 21 North Third St., Minneapolis 1.

The Maico "Top Secret" Hearing Aid, Model J, is an electric hearing aid of conventional form except for the position of the microphone, which is mounted on the top of the case facing upward. The microphone grill is deeply recessed. This is intended to reduce clothing noise. The case measures 74 by 45 (greatest thickness) by 28 mm., and is somewhat wedge-shaped. The weight is 92 gm. without batteries and 123 gm. with batteries. Both magnetic and crystal receivers are available.

The Council obtained evidence from acceptable sources that the workmanship and performance were good and that the instrument satisfied the published minimum requirements of the Council for acceptance of hearing aids. The Council on Physical Medicine and Rehabilitation voted to include the Maico "Top Secret" Hearing Aid, Model J, in its list of accepted devices.



Maico Hearing Aid, Model J

INCIDENCE OF PULMONARY CARCINOMA

Numerous surveys have indicated that the incidence of carcinoma of the lung has been increasing in recent years. There is no general agreement, however, as to whether this increase is real and absolute or merely apparent and relative, owing to such factors as better diagnosis, increasing clinical awareness of the condition, and the increase in life expectancy.

A recent report on the incidence of pulmonary carcinoma in 36,864 autopsies performed during the period 1918-1946 at the Los Angeles County Hospital shows that in the area served by this hospital the increase of the disease was real, absolute, and disproportionately greater than the increase in cancer in general.[1] In the 36,864 necropsies, a total of 6,023 malignant tumors were found which with few exceptions were the cause of death. Of these tumors, 508 were carcinomas of the lung, an incidence of 1.4% in all necropsies and 8.4% of all malignant neoplasms. During the period 1918-1922, cancer was reported in 11.2% of all autopsies, while during the period 1943-1946 it was reported in 20.7% of all autopsies. Carcinoma of the lung showed an even greater increase than cancer as a whole. No cases were reported during the period 1918-1922, but in succeeding years the incidence rose progressively. Thus, during the period 1923-1927, carcinoma of the lung was found in 0.6% of all autopsies and constituted 4.3% of all tumors found, while in 1943-1946 corresponding figures were 2.3% and 11.3%. When the incidence of lung carcinoma in consecutive groups of 500 malignant tumors was analyzed, a gradually increasing trend was apparent, with 10 lung cancers in the first 500 and 66 in the last. Again, when necropsies were divided into groups of 1,000, a gradual increase in lung carcinoma was apparent throughout the 32 years, with an acceleration in the period 1939-1943. Furthermore, the necropsy rate for lung carcinoma in relation to hospital admissions increased more than twice as much as did that for all cancers combined. In contrast with the findings in carcinoma of the lung, comparable increases were not found for carcinoma of the stomach, large intestine, or pancreas, or for intracranial tumors.

There was little change in the proportion of males in the necropsy population; hence it was concluded that the increase of lung carcinoma was not explicable on the basis of a shift in sex ratio. There was a gradual increase in the average age; however, if the increase of carcinoma of the lung were due solely to aging of the population, one would expect even greater increases in cancer of the large intestine and pancreas since the peak incidence of these diseases is at a later age than that of carcinoma of the lung.

Evidence was also presented to show that the increased incidence of lung carcinoma could not be attributed to improve recognition by the pathologist, to a rising necropsy-permit rate, or to a greater interest in obtaining permits in cases clinically diagnosed. Furthermore, there was no evidence indicating either a large-scale selective referral to the hospital of lung cancer cases or of selective immigration of persons having pulmonic diseases into Los Angeles County, while no known occupational hazards for lung cancer were unduly represented in the hospital population.

This apparently real increase in carcinoma of the lung in the Los Angeles hospital is in contrast to the very slight increase reported by Steiner in 5,515 necropsies performed between 1902 and 1941 at the University of Chicago.[2] It was felt that the findings represented a real difference in the two materials and possibly in the two communities, thus suggesting a condition existing in the entire population of the county. It was felt that the smog condition was of too recent occurrence to account for the increase, unless previous data on the latent period for induction of lung cancer are inapplicable. In concluding their report, the authors emphasize that, regardless of whether the incidence of lung carcinoma is increasing or has increased at all, its present level is so high that it constitutes a major public health problem requiring appropriate clinical, experimental, and statistical studies.

BACILLARY DYSENTERY

Bacillary dysentery is a disease that has been widely distributed throughout the world from time immemorial. It was known to the ancients, as shown in Hippocrates' "Epidemeion." Until the discovery of the specific causative agent by Shiga in 1898 and Flexner in 1900, very little advance was made in our knowledge of the disease. The greatest progress has been made during the last two decades, particularly in the fields of pathology and bacteriology. For example, patients may have lesions of the intestine at sigmoidoscopy with little or no clinical symptoms and signs. Yet these patients are just as infective as those who are sick. No longer is pathogenicity determined by the particular strain present, of which there are at least 19 different types. The Sonne-Duval bacillus, once regarded as causing a rather benign dysentery in children, may be as virulent as the time-honored Shiga-Kruse infection. Any dysentery strain may play havoc in a population hitherto free of the disease, and in endemic areas susceptibility appears to return about every 20 years.

The disease has been traced from the acute to the chronic phase in the same human being, so that the chronic type is now better understood. While the etiology of chronic distal ileitis or chronic ulcerative colitis is still controversial, there appears to be no doubt that cases have followed acute bacillary dysentery. In the Jersey City epidemic of Flexner dysentery in 1934, chronic distal ileitis or chronic ulcerative colitis developed in 10.7%. Whether all cases follow bacillary dysentery cannot be proved, since many of the patients are seen for the first time one or more years after onset, when the dysentery organisms are no longer present and the original acute attack has been forgotten.

---

[1] Steiner, P. E.; Butt, E. M., and Edmondson, H. A.: Pulmonary Carcinoma Revealed at Necropsy, with Reference to Increasing Incidence in the Los Angeles County Hospital, J. Nat. Cancer Inst. **11**: 497, 1950.

[2] Steiner, P. E.: Incidence of Primary Carcinoma of the Lung with Special Reference to Its Increase, Arch. Path. **37**: 185, 1944

Bacillary dysentery continues to be a great "war disease"; it is transmitted by food, fingers, and flies and remains a serious hazard for civilians despite the sulfonamides and antibiotics.

THE CONTROL OF MALARIA

Within the lifetime of many physicians now in practice a tremendous change in the incidence of and mortality from malaria has occurred, not only in the United States but also in many other countries. Both the cause of the disease, first described by Laveran, the French Army surgeon in 1880, and its insect vectors, the Anopheles group of mosquitoes, incriminated by Ronald Ross and the Italian malariologists 10 years later, have been known for well over 50 years. With these discoveries as a basis for preventive action, it was obvious that this must take the form of eradication of the vector or sterilization of the blood of human carriers, but preferably both.

As Faust[1] has shown, there is no reasonable doubt that Anopheles mosquitoes existed in America long before the Columbian Era and that the Plasmodium was introduced by infected Europeans and African slaves. The spread of the disease from original foci in the eastern United States was mainly the result of the migrations of the pioneers, and it was known by 1850 to exist from New England and the southeastern states to California and the Columbia River Valley. In certain areas—northernmost New England, the Allegheny highlands, the Rocky Mountains, the Great Inland Desert, and the Western Sierras—it was not known to occur. Naturally it flourished best in this country in the southern states, where the Anopheles was able to breed for eight to 10 months of the year, as contrasted with the three or four warm summer months of the northern area.

A complicating factor in the distribution and survival of the disease was war, for in the conflict in the states in 1861-1865, northern soldiers returning from service in the southern states carried the infection; in the Spanish-American War many soldiers serving in Cuba and the Philippines were infected; and in World War II many northern troops were trained in the South and much of the fighting occurred in districts in the Pacific more or less heavily infected with malaria. Returning soldiers were frequently carriers, despite the prophylactic and curative use of antimalarial drugs.

The control of malaria is a good example of the fact that such problems are not merely medical but also economic. The eradication of Anopheles mosquitoes requires large sums of money not only for drainage projects but also for the purchase and proper distribution of insecticides and larvicides. This is an annual performance and needs trained personnel for adequate accomplishment. In periods of financial depression there is diminished expenditure for mosquito control and inability of the poorer segments of the population to procure properly balanced diets, with resulting lessened resistance to infection. Economic factors were doubtless responsible for the fact that widespread attempts to control malaria were not made until many years after the knowledge necessary to formulate prophylactic measures was available.

Before the war in Korea, the disease was largely under control, but one must not overlook the fact that many malaria-carrying soldiers will return from this area and that there must be constant watchfulness to see that this does not result in a flare-up in the incidence of the disease.

BCG VACCINATION

BCG vaccination has been used for more than a quarter of a century. Its true role in the prevention of tuberculosis still remains a subject of controversy. A status report has been published in THE JOURNAL[1] by the Council on Pharmacy and Chemistry. Though it is impossible to conduct ideal experimental BCG studies in man, such studies can provide evidence approaching that sought in animal experimentation. Such evidence is reported by Dahlström and Difs,[2] who investigated the incidence of various types of tuberculous disease among tuberculin-negative Swedish Army conscripts, whom they divided into two comparable groups, one of which was vaccinated with BCG. The results indicate that the incidence of not only primary tuberculosis but also exudative tuberculous pleurisy and early postprimary destructive pulmonary tuberculosis was significantly reduced in the vaccinated (36,235) compared with the nonvaccinated (25,239) soldiers. This is the first time it has been shown that the postprimary tuberculous diseases may be prevented by BCG vaccination. The number of deaths from tuberculosis was also significantly reduced. Since the vast majority of soldiers were infected while in military service, the Swedish investigators conclude that it "is therefore important to carry out vaccination, so far as possible, in such good time that protection will have developed before the conscript enters military service."

BCG vaccination seems to be gaining favor in some quarters for the prophylaxis of tuberculosis, but the disease should not be regarded as being in the class of typhoid; so far as control is concerned, much remains to be done. Other careful studies of tuberculosis prophylaxis with BCG vaccination should be instituted with the ever essential tuberculin testing and sane interpretation.

MEDICAL NEWS

COLORADO

Annual Cancer Seminar.—This seminar will be held at the Broadmoor Hotel, Colorado Springs, Sept. 8, under the sponsorship of the Penrose Cancer Hospital and the College of American Pathologists. Dr. Arthur P. Stout, professor of pathology at Columbia University, New York, and Dr. Philip J. Hodes, professor of radiology at the University of Pennsylvania, Philadelphia, will jointly conduct the seminar. Dr. Leo H. Garland, clinical professor of radiology, Stanford University School of Medicine, San Francisco, will speak at the banquet. Fifteen problem cases of thoracic lesions having some relation to the field of tumors have been chosen. A photographic reproduction of the roentgenograms and a clinical summary of each case will be submitted to the participating radiologists, who will be invited to submit their diagnoses on an unsigned card, for purposes of tabulation. A set of slides of the same cases, with the same clinical summaries, will be submitted to the participating pathologists. All those interested may attend. There will be no registration fee; hotel reservations should be requested in advance. The meeting will be called at 9 a. m.

CONNECTICUT

Health Exhibits at County Fairs.—The Connecticut State Medical Society's committee on rural medical service will sponsor a health exhibit for display at a number of Connecticut's fairs in August and September. The project was inaugurated last year when a three-panel exhibit presented information on physician distribution in rural areas and voluntary health insurance. Success of that project has encouraged its continuance. This year's exhibit will feature a display of health pamphlets for distribution to fair patrons. Members of the committee are Drs. Edward H. Basden, Willimantic; Gaert S. Gudernatsch, Sharon; Enos J. O'Connell, Unionville; William H. Pomeroy, Poquonock, and William H. Upson, Suffield.

GEORGIA

Personal.—Dr. William L. Champion, Atlanta, said to be the oldest urologist in Georgia, on July 7 was honor guest at a dinner given by an associate, Dr. Major F. Fowler, Atlanta, at the East Lake Country Club. All members of Fulton County Medical Society were invited to the dinner, which marked Dr. Champion's 83rd birthday.

Hospital Dedicated.—The new 112-bed Hall County Hospital at Gainesville was dedicated by Gov. Herman Talmadge on Aug. 1. Heading the medical staff will be Dr. Cleveland D. Whelchel, Gainesville, with Drs. Clarence G. Butler, Walter R. Garner, Herbert E. Valentine Jr., Bradley B. Davis, and Clyde W. Whitworth, all of Gainesville, composing the executive committee. Drs. Davis and Whitworth are vice-chief of staff and secretary-treasurer, respectively.

ILLINOIS

Narcotic Violation.—Dr. Claude E. Gilliatt, Allendale, pleaded *nolo contendere* to a violation of the federal narcotic law in the United States District Court at Danville, and on June 11 he was fined $150 and costs.

University to Operate Neuropsychiatric Institute.—A bill transferring the Illinois Neuropsychiatric Institute in Chicago to the University of Illinois from the former joint operation by the university and the State Department of Public Welfare has been passed by the Illinois General Assembly and signed by Governor Stevenson. It includes an appropriation of $1,405,700 to the University of Illinois for the operation and maintenance of the institute for the biennium beginning July 1, 1951. Professional services were in charge of Dr. Eric Oldberg and Dr. Francis J. Gerty of the University of Illinois College of Medicine. Funds for nursing service were appropriated to and paid out by the State Department of Public Welfare. Funds for the physical plant, operation of maintenance, and for food service were appropriated to the department, but the services were provided by the university. Under the new plan, all activities and operations of the institute are vested in the University of Illinois. This change was recommended by the Shaefer Commission on State Reorganization and was concurred in by both the university and the State Department of Public Welfare. Dr. Oldberg will serve as director of the division of neurology and neurological surgery and Dr. Gerty as director of the division of psychiatry. The plan will simplify business procedures in the university, the department, and state fiscal offices. The purpose of the institute, as stated by the University of Illinois Board of Trustees, is to act as a liaison between the Illinois State Mental Health Service and the University of Illinois in a cooperative effort to improve the quality of the medical personnel dealing with the patients committed to their care, and to seek new and improved methods of treatment. The operation of the State Psychopathic Institute and the Pathological Laboratory, which are housed in the Illinois Neuropsychiatric Institute, will remain under the State Department of Public Welfare. Dr. Percival Bailey, professor of neurology and neurological surgery at the university, who previously served as executive officer of the institute for the State Department of Public Welfare, will be in charge of these activities for the department. The university, however, will assume the physical operation of the space used by these activities.

Chicago

Dr. Mote Moves to Philadelphia.—Dr. John R. Mote, research scientist responsible for much of the clinical development of corticotrophin (ACTH), has joined the Research and Development Laboratories of Smith, Kline and French Laboratories in Philadelphia as medical director. Formerly medical director and assistant general manager of Armour Laboratories, Dr. Mote will assume his new post with the Philadelphia pharmaceutical research and manufacturing firm in September.

Televised Postgraduate Conference.—The Third Annual Televised Postgraduate Conference in Obstetrics and Gynecology will be given Sept. 24-28 at Lewis Memorial Maternity Hospital. It will be presented by the department of obstetrics and gynecology of the Stritch School of Medicine of Loyola University under the chairmanship of Dr. Herbert E. Schmitz. The conference will include demonstrations of obstetrical procedures and gynecological surgery. The Radio Corporation of America will install television screens throughout the hospital to assure clear viewing and listening. There is no registration fee.

Appoint Dean of Indian Medical College.—Dr. Carroll L. Birch, professor of medicine at the University of Illinois, has been appointed dean of the Lady Hardinge Medical College for Women at New Delhi, India, for one year. The 100-year-old college, endowed by a British noblewoman, is the only Indian medical institution for the training of women. Dr. Birch's specific assignment will be to train a replacement to take over the duties of dean of the college. She also will prepare recommendations for the reorganization of teaching methods and curricula to raise school standards to meet those of modern medical educational institutions.

Research Grants.—Grants for research totalling more than $18,000 have recently been received by the Chicago Medical School. The Eli Lilly Research Laboratories gave $6,000 for work in experimental diabetes under the direction of Dr. Piero P. Foa, associate professor of physiology and pharmacology. The Chicago Heart Association, for the year July 1 to June 30, 1952, made grants of $2,000 and $6,800 for studies to be conducted under the direction of Dr. Aldo A. Luisada, program director of cardiology and assistant professor of medicine, and $4,000 for research directed by Dr. George J. Scheff, associate professor of microbiology.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

INDIANA

Ray Smith Dies.—Ray E. Smith, executive secretary of the Indiana State Medical Association since 1946, died Aug. 4 at his home in Indianapolis, aged 54, of a heart attack. A former newspaper man, and executive secretary to Gov. Henry F. Schricker in 1941, Mr. Smith had served as secretary of the Indianapolis Medical Society and served on a part-time basis for the state medical society at the same time. He was on the State Board of Tax Commission and was recently appointed to the Indiana Council of Mental Health. Last spring he was appointed to the lay public relations advisory committee of the American Medical Association. Mr. Smith was a past president of the Indiana Editorial Association and was a member of Sigma Delta Chi and the Indianapolis Press Club.

KENTUCKY

Historic Medical Gavel.—The Kentucky Surgical Society has received from its first president, Dr. Charles A. Vance, Lexington, a gavel made from wood having historical significance. The wood was collected by the late Dr. Joseph A. Stucky, Lexington, from the first building of the Transylvania Medical College in Lexington, from the home of Dr. Ephraim McDowell, Danville, and from a tree planted by Dr. McDowell in his backyard. Three gavels were made from these sources, one of which Dr. Vance has presented to the Southern Surgical Association and the other to the Southern Medical Association.

Hospital Honors Staff Veteran.—Dr. Michael J. Henry, Louisville, was recently honored by St. Joseph Infirmary at a dinner at the hospital in observance of his 50th anniversary of services. Dr. Henry has been closely connected with St. Joseph infirmary during most of the 50 years since his first job there in 1901 when at the age of 11 he was hired to do odd jobs about the hospital. He has been chairman of the City-County Health Board and president of the Jefferson County Medical Society. Last year he was named to the board of governors of the American College of Surgeons.

LOUISIANA

Center for the Hard of Hearing.—An anonymous gift of $5,000 will help establish a center for the hard of hearing at the Tulane University of Louisiana School of Medicine, New Orleans. Plans call for immediate construction of the center on the sixth floor of Hutchinson Memorial Medical Building. Establishment of a research program in rehabilitation of the deaf, and staffing of the center with research fellows in connection with this program, are planned for the future. Operating as a diagnostic clinic, the center will provide specific services not available in the area which Tulane serves.

MASSACHUSETTS

Personals.—Dr. Thomas S. Sexton has been appointed medical director of the Massachusetts Mutual Life Insurance Company of Springfield.——Dr. James L. Whittenberger, associate professor and head of the physiology department for four years, has been promoted to professor of physiology at the Harvard School of Public Health, Boston.

Appointments at Harvard.—Dr. Otto Krayer has been promoted to professor of pharmacology in the Harvard Medical School, Boston. As head of the department, he also will continue to instruct students and to do research. Dr. Krayer, who has been associate professor of comparative pharmacology since 1940, taught pharmacology at the American University of Beirut, Lebanon, before joining the staff at Harvard in 1937. He is a member of the Pharmacological Study Section of the United States Public Health Service and is on the editorial staff of "Pharmacological Reviews." He served as a member of the Unitarian Service Committee's medical mission to Czechoslovakia in 1946 and as chairman of the Unitarian mission to Germany in 1948. Other appointments include Dr. Jordi Folch-Pi, who becomes associate professor of biological chemistry at McLean Hospital in Waverley, continuing as chief of the biochemical laboratory there, and Dr. Nathan Bill Talbot, who becomes associate professor of pediatrics at Massachusetts General Hospital. Both doctors will carry on their research and teaching activities at the hospitals. Dr. Raymond Delacy Adams has been promoted from assistant professor to associate clinical professor of neurology and chief of the neurological service at Massachusetts General Hospital. He succeeds Dr. Charles S. Kubik in both positions. Dr. Kubik, who has now become lecturer on neuropathology, will continue his neurological research and practice at the hospital.

MICHIGAN

Continuation Courses.—Wayne University College of Medicine, Detroit, is giving postgraduate continuation courses Sept. 10 to Dec. 1, which are open to all qualifying persons. The subjects include microbiology, physiological chemistry, physiology and pharmacology, pathology, dermatology, internal medicine, surgery, and obstetrics. A postgraduate course in the early detection of cancer is to be given throughout the year. It will utilize the facilities of Yates Memorial Clinic, Detroit Receiving Hospital and the Veterans Administration Hospital in Dearborn. Registration should be made with the office of Postgraduate Medical Education at the College of Medicine, 1512 St. Antoine, before Sept. 8. Tuition for the last course is $50 per quarter, and the class is limited to 15.

MISSOURI

General Practitioners Study Club.—The following programs for 1951 featuring local physicians have been arranged by the General Practitioners Study Club of Greater St. Louis:

Sept. 19, Roy V. Boedeker, Practical Procedures in Gynecology for Treatment in the General Practitioners Office.
Oct. 17, James F. Dowd, Treatment of Common Injuries Resulting from Automobile Accidents.
Nov. 21, Adolph C. Lange, Ophthalmic Procedures for the General Practitioner.
Dec. 19, Leo J. LeBlanc, Office Management of Some of the Common Anorectal Diseases.

MONTANA

General Practitioners Meeting.—The Montana chapter of the American Academy of General Practice will hold its annual meeting at the Rainbow Hotel, Great Falls, Sept. 13. Following a dinner meeting at 7 p. m. and a business meeting, Dr. Mark H. Mothersill of the research staff of Eli Lilly and Company, Indianapolis, will speak on "General Practitioners and Allergic Reactions." All physicians are invited to attend. Dr. James A. Mueller, Lewistown, asks that all who plan to attend make their reservation with him not later than Sept. 1.

NEW YORK

Infectious Hepatitis.—Dr. Milton Tully, New York State Department of Health, has reported an outbreak of infectious hepatitis in rural Chemung County. Twenty cases occurred from Jan. 11 to July 8, half of them in June. Cases were found principally in school children and were linked by personal contact.

Bulbar Poliomyelitis Center.—A new center for the clinical study of bulbar and respiratory poliomyelitis will be established at the University of Buffalo's Chronic Disease Research Institute under a grant from the National Foundation for Infantile Paralysis. The respirator center, one of four of its kind to be set up in the United States with March of Dimes funds, will have a capacity of at least ten respirators and will engage in research and clinical investigations on the recovery and rehabilitation of serious poliomyelitis cases. In a ceremony at the institute July 25 the foundation presented to the university its first check of $41,048 for the project. The medical school will immediately begin to prepare, equip, and staff the unit. Dr. Walter T. Zimdahl, medical director of the institute, will co-ordinate the activities of the center with those of the institute. The National Foundation said it selected Buffalo as the location of the new center on the recommendation of the New York State Coordinating Council of Poliomyelitis. Other respirator units sponsored by the foundation are now operating at the Children's Medical Center of Boston, Wellesley Hills, Mass.; at Jefferson Davis Hospital, Houston, Texas, and at University Hospital, Ann Arbor, Mich. In the joint announcement issued by the National Foundation and the University of Buffalo, the purpose of the center was described as three-fold:

1. To determine through special patient evaluation methods and by newer clinical investigative techniques and equipment how best to wean patients from iron lungs and enable them to be cared for at home, with the provision of physical therapists, occupational therapists, and psychological and medical social services to assist in the maximal rehabilitation of patients.
2. To provide opportunity for special study for doctors, nurses, and physical therapists, and more intensive training for resident physicians and medical students in the field of respiratory involvement in poliomyelitis, and to provide consultation and assistive services to hospitals in upstate New York.
3. To evaluate equipment used in diagnosis and treatment, and to cooperate in efforts to develop improvements.

New York City

Hillman Health Center to Expand.—This health center of the Amalgamated Clothing Workers, C. I. O., which opened four months ago (The Journal, May 26, p. 384), must be redesigned to permit the handling of a larger number of patients. The six-story building will be enlarged to include installation of advanced x-ray equipment and a research laboratory for studies in arteriosclerosis. Each week about 1,800 clothing workers go to the center for examination and treatment.

State University Appointments.—James O. Pinkston, Ph.D., has been appointed lecturer in the department of physiology at the State University of New York College of Medicine at New York City. From 1943 to 1950 Dr. Pinkston was dean of the medical division, American University of Beirut, Lebanon, where he had previously served as associate professor and chairman of the department of pharmacology and later as professor and chairman of the department of physiology. Recently he was on the staff of Cornell University Medical College.

OREGON

Rural Health Council.—Twenty-six state-wide organizations concerned with the health of the rural population of the state have organized the Oregon Health Council. Objectives of the council are to bring together representatives of state organizations and agencies which are now conducting programs affecting rural health for the purpose of discussing and exchanging views, and developing recommendations for improving rural health, and to encourage and stimulate the establishment of county or community health councils or committees. Chairman of the council is Dr. Howard A. Wells, Redmond, chairman of the Oregon State Medical Society committee on rural medical service; vice-chairman, Mrs. Amy S. Larkin, Portland, of the farm home administration of the U. S. Department of Agriculture, and secretary, Mrs. Mable C. Mack, Corvallis, Oregon State College Extension Service.

PENNSYLVANIA

Psychiatric Speaker's Bureau.—The Pennsylvania Psychiatric Society has established a speaker's bureau which will furnish, on request, psychiatrists to speak before lay and professional groups. Requests should be addressed to Dr. Stanley W. Conrad, 1822 Spruce St., Philadelphia.

Heart Association Fellowship.—The First Fellowship of the Heart Association of Southeastern Pennsylvania, amounting to an annual grant of $3,000 a year, has been awarded to Dr. Arthur Goldman, Philadelphia, who will work under the jurisdiction of Drs. Thomas M. McMillan and Samuel Bellet, Philadelphia General Hospital.

The Philadelphia Heart Association has changed its name to the Heart Association of Southeastern Pennsylvania because it serves Bucks, Chester, Delaware, and Montgomery counties as well as Philadelphia County. The officers are Dr. Lauritz S. Ylvisaker, president; Dr. Warner F. Haldeman, vice president; Mr. William T. Carter, treasurer, and Dr. Paul H. Parker, secretary.

Philadelphia

New Type Contagious Institution.—In July Philadelphia Hospital for Contagious Diseases opened facilities that will enable the simultaneous hospitalization of various types of contagious diseases. Patients will be quartered in units of two and five beds, each having its own bathing and lavatory facilities, and each with a combined heating and ventilating system capable of changing the air at the rate of 750 cubic feet per minute. A total of 54 patients suffering from various diseases will be cared for. At any time the ward door is opened the lower air pressure inside pulls the air into the ward, thus preventing any contaminated air from finding its way into the corridor. Dedication of this West Wing Observation Building, as it is to be known, was held July 10 with Dr. Rufus S. Reeves, director of public health, presiding.

WASHINGTON

Report of Plague Specimens.—Dr. Vernon B. Link, Western Communicable Disease Center Laboratory, has reported the following specimens obtained in Lincoln County were proved positive for plague: (1) Specimen No. 51-WB-26, consisting of 39 fleas (Megabothris clantoni clantoni) from 43 sagebrush voles (Lagurus curtatus) which were trapped 12 miles southeast of Wilbur, (9.6 miles south on State Highway 4B and then 5 miles east on county road) on July 5; and (2) Specimen No. 51-WB-27, consisting of 137 fleas (61 Thrassis gladiolis johnsoni and 76 Megabothris clantoni clantoni) from 38 Lagurus curtatus, trapped 17 miles north of Odessa, on State Highway No. 4B, on July 7.

GENERAL

Society Election.—At its annual meeting the American Medical Women's Association, Inc., elected Dr. Amey Chappell, Atlanta, president; Dr. Evangeline E. Stenhouse, Chicago, president-elect; Dr. Adelaide Romaine, New York, treasurer; Dr. Esther C. Marting, Cincinnati, recording secretary, and Dr. Irma C. Henderson-Smathers, Asheville, N. C., corresponding secretary.

Dr. Faulkner Heads Specialty Board.—Dr. Robert L. Faulkner, Cleveland, has been elected secretary-treasurer of the American Board of Obstetrics and Gynecology, to succeed the late Dr. Paul Titus. Dr. Lawrence M. Randall, Rochester, Minn., has been elected assistant secretary, and Dr. Herbert E. Schmitz, Chicago, a director of the board. Effective Aug. 10, the office of the board will be located at 2105 Adelbert Road, Cleveland 6. All correspondence should be directed to Dr. Faulkner at this address.

Dr. Hussey Named to Editorial Staff.—Dr. Hugh H. Hussey, associate professor of medicine at Georgetown University, Washington, D. C., has been appointed associate editor of *GP*, published by the American Academy of General Practice. Dr. Hussey has for years been associate editor of the *Medical Annals of the District of Columbia*. He is author of the section on "Supportive and Symptomatic Therapy" in the textbook "Fundamentals of Internal Medicine" now in its third edition. He carries on a consultation practice in Washington and is a member of the staff of Gallinger Municipal Hospital and the Georgetown University Hospital and is senior consultant on vascular diseases at the Mount Alto Veterans Hospital.

Tuberculosis Service Workers' Course.—The National Tuberculosis Association will conduct a general training course for new professional workers at Roycroft Inn, East Aurora, New York, Sept. 4-29. The course is open to staff members of state and local tuberculosis associations who have had at least one month of experience and not more than 10 months, and to college graduates seeking careers in the tuberculosis field. The course is designed to acquaint new workers with basic concepts and techniques in voluntary tuberculosis association work. Field trips will supplement the formal curriculum, which includes lectures on all phases of social service work for the tuberculous.

Gold Heart Awards.—These awards for outstanding contributions to cardiovascular medicine or the American Heart Association were presented at the association's annual dinner in Atlantic City in June to Drs. James B. Herrick, Frank N. Wilson, and Harold M. Marvin. Dr. Herrick, emeritus professor of medicine at the University of Chicago and the University of Illinois, was honored for his work on coronary thrombosis. Dr. Wilson, professor of medicine at the University of Michigan, received the award for his investigations in the field of electrocardiography. Dr. Marvin, New Haven, Conn., received the Gold Heart for his many years of service to the association, including the presidency in 1949-1950.

Prevalence of *Poliomyelitis.*—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States in the weeks ended as indicated:

Area	Aug. 4, 1951	Aug. 5, 1950

Mississippi Valley Society Meetings.—The Mississippi Valley Medical Society will hold its annual meeting at the Hotel Pere Marquette, Peoria, Ill., Sept. 19-21, under the presidency of Dr. Ralph McReynolds, Quincy, Ill. Thirty-two scientific papers will be presented. The visiting speaker will be Dr. Oscar C. Hansen-Pruss, professor of medicine at The Duke University, Durham, N. C. There will be round table luncheons Thursday and Friday. Speakers at the evening fellowship hour, banquet, and entertainment on Thursday will be Drs. C. Paul White, Kewanee, Ill.; C. Edgar Virden, Kansas City, Mo.; Donald C. Conzett, Dubuque, Iowa, and Alexander Baird, Ph.D., Peoria, Ill. There is no registration fee.

The American Medical Writers' Association will meet at the hotel on Sept. 19 under the presidency of Dr. Julius Jensen, St. Louis. The session, beginning in the afternoon, will be addressed by Dr. Richard M. Hewitt, head of the section of publications, Mayo Clinic, Rochester, Minn. Other speakers will be Miss Marguerite Stadelhofer, managing editor of C. V. Mosby Company, medical publishers, who will speak on "The Making of Medical Books." At the evening session Dr. Ralph H. Major, professor of medicine and of the history of medicine at the University of Kansas City, Kansas City, Mo., will speak on "Some of the Great Books of Medicine."

American Cancer Society Fellowship Awards.—Three Chicago scientists have been awarded fellowships for cancer research totaling $13,000 for studies of growth processes in plants and animals. Dr. John M. Marshall Jr. will study for one year at the Carlsberg Laboratory in Copenhagen, Denmark, where he will investigate the method by which plant constituents are isolated and purified. Robert C. Barnett, Ph.D., and Richard M. Klein, Ph.D., both of the University of Chicago, will conduct their research there. These scientists were selected from applicants in all parts of the country and were recommended for American Cancer Society fellowships by the Committee on Growth of the National Research Council.

FOREIGN

Communicable Diseases.—According to reports received by the regional office of the World Health Organization, an outbreak of poliomyelitis has been in progress in Mexico City since the first part of May. Since then over 400 cases have been reported. The peak of the outbreak apparently was reached in the week ending June 23 when there were 100 new cases. For the weeks ending June 30 and July 7, there were 54 and 40 cases, respectively, reported. For the week ending July 14, there were 12 new cases in the city of Birmingham, England.

A high prevalence of diphtheria continues in Rio de Janeiro, Brazil, 86 cases with nine deaths being reported for the three-week period ending on July 7. In Santiago, Chile, 45 cases and one death occurred in the week ending July 7; and in San Jose, Costa Rica, there were 10 cases in the second week of July. In Bangkok, Thailand, and in Singapore, 20 and eight cases, respectively, were reported for one week early in July. According to a World Health Organization report, there were 1,419 cases of brucellosis in Italy in May as compared with 1,172 in April. During the first two weeks of June 37 cases were reported on the Island of Malta and Gozo. In the cities of Spain with less than 20,000 population, there was a total of 618 cases with five deaths reported in a seven-week period ending April 14. In cities with more than 20,000 population only 17 cases were reported in the same period.

MEETINGS

Ambulatory Fracture Association, *Arrowhead Springs Hotel*, San Bernardino, Calif., Oct. 8-11. Dr. H. W. Wellmerling, 626 Griesheim Bldg., Bloomington, Ill., Secretary.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, The Homestead, Hot Springs, Va., Sept. 6-8. Dr. William F. Mengert, 2211 Oak Lawn Ave., Dallas, Texas, Secretary.

American Congress of Physical Medicine, Shirley-Savoy Hotel, Denver, Sept. 4-8. Dr. Walter J. Zeiter, 2020 E. 93d St., Cleveland 6, Executive Director.

American Hospital Association, St. Louis, Sept. 17-20. Mr. George Bugbee, 18 E. Division St., Chicago 10, Executive Director.

American Roentgen Ray Society, Washington, D. C., Sept. 25-28. Dr. Barton R. Young, Germantown Hospital, Philadelphia 44, Secretary.

American Society of Maxillofacial Surgeons, Drake Hotel, Chicago, Sept. 23-26. Dr. Casper M. Epsteen, 25 E. Washington St., Chicago 2, Secretary.

Association of Military Surgeons of the United States, Palmer House, Chicago, Oct. 8-10. Colonel James M. Phalen, Armed Forces Institute of Pathology, Washington 25, D. C., Secretary.

Colorado State Medical Society, Denver, Sept. 18-21. Mr. Harvey T. *Sethman, 1612 Tremont Place*, Denver 2, Executive Secretary.

Delaware, Medical Society of, Wilmington, Oct. 8-10. Dr. Andrew H. Gehret, 1007 Park Place, Wilmington, Secretary.

District of Columbia, Medical Society of, Hotel Statler, Washington, Oct. 1-3. Mr. Theodore Wiprud, 1718 M St. N.W., Washington, Secretary.

Kansas City Southwest Clinical Society, Municipal Auditorium, Kansas City, Mo., Oct. 1-4. Dr. Maxwell G. Berry, 630 Shukert Bldg., Kansas City, Mo., Director of Clinics.

Kentucky State Medical Association, Columbian Auditorium, Louisville, Oct. 2-5. Dr. Bruce Underwood, 620 S. Third St., Louisville 2, Secretary.

Michigan State Medical Society, Grand Rapids, Sept. 26-28. Dr. L. Fernald Foster, 606 Townsend St., Lansing 15, Secretary.

Mississippi Valley Medical Society, Peoria, Ill., Sept. 19-21. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

Montana Medical Association, Great Falls, Sept. 13-16. Mr. L. R. Hegland, 104 N. Broadway, Billings, Executive Secretary.

Nashville Postgraduate Medical Assembly, Maxwell House, Nashville, Tenn., Oct. 3-5. Dr. W. G. Kennon Jr., 647 Doctors Bldg., Nashville 3, Secretary.

National Medical Association, Philadelphia, Aug. 20-24. Dr. John T. Givens, 1108 Church St., Norfolk 10, Va., General Secretary.

Neurosurgical Society of America, Sun Valley, Idaho, Sept. 12-14. Dr. C. D. Hawkes, 22 N. Manassas St., Memphis 5, Tenn., Secretary.

Nevada State Medical Association, Riverside Hotel, Reno, Sept. 13-15. Dr. Wesley W. Hall, 307 W. Sixth St., Reno, Secretary.

New Hampshire Medical Society, Equinox House, Manchester, Vermont, Sept. 30-Oct. 2. Dr. Deering G. Smith, 44 Chester St., Nashua, Secretary.

Northeastern Section, Southeastern Surgical Congress, Lord Baltimore Hotel, Baltimore, Sept. 13-15. Dr. W. Raymond McKenzie, Medical Arts Bldg., Baltimore 1, Secretary.

North Texas-Southern Oklahoma Fall Clinical Conference, Wichita Falls, Texas, Sept. 19. Dr. W. L. Powers, 517 Hamilton Bldg., Wichita Falls, Chairman.

Oregon State Medical Society, Masonic Temple, Portland, Oct. 10-13. Dr. Robert F. Miller, 833 S.W. Eleventh Ave., Portland 5, Secretary.

Pennsylvania, Medical Society of the State of, Pittsburgh, Sept. 16-20. Dr. Walter F. Donaldson, 500 Penn Ave., Pittsburgh 22, Secretary.

Reno Surgical Society Conference, Riverside Hotel, Reno, Nev., Aug. 23-25. Dr. Olin C. Moulton, 130 N. Virginia St., Reno, Nev., Chairman.

Southwestern Surgical Congress, Hotel Jefferson, St. Louis, Sept. 24-26. Dr. C. R. Rountree, 1227 Classen St., Oklahoma City 3, Secretary.

Texas Academy of General Practice, Shamrock Hotel, Houston, Texas, Sept. 10-11. Dr. B. H. Bayer, 104 E. 20th St., Houston 8, Secretary.

U. S. Chapter, International College of Surgeons, Palmer House, Chicago, Sept. 10-14. Dr. Arnold S. Jackson, 1516 Lake Shore Drive, Chicago, Executive Secretary.

Utah State Medical Association, Salt Lake City, Sept. 13-15. Dr. T. C. Weggeland, 42 S. Fifth East St., Salt Lake City, Secretary.

Vermont State Medical Society. Equinox House, Manchester, Sept. 30-Oct. 2. Dr. James P. Hammond, 542 Main St., Bennington, Secretary.

Virginia, Medical Society of, Virginia Beach, Oct. 7-10. Mr. Richard H. Nash, 1105 W. Franklin St., Richmond, Executive Secretary.

Washington State Medical Association, Olympic Hotel, Seattle, Sept. 9-12. Dr. James W. Haviland, 338 White-Henry-Stuart Bldg., Seattle, Secretary.

Western Society of Electro-Encephalography, Olympic Hotel, Seattle, Sept. 7-8. Dr. Nicholas A. Bercel, 450 N. Bedford Drive, Beverly Hills, Calif., Secretary.

Wiscnosin, State Medical Society of, Hotel Schroeder and Milwaukee Auditorium, Milwaukee, Oct. 1-3. Mr. Charles H. Crownhart, 704 E. Gorham St., Madison 3, Secretary.

Wyoming State Medical Society, Rock Springs, Sept. 27-29. Dr. Glenn W. Koford, 2020 Carey Ave., Cheyenne, Secretary.

INTERNATIONAL

European Congress on Rheumatism, Barcelona, Spain, Sept. 24-27. Dr. Gunnar Edströn, Lund, Sweden, Secretary.

General Practitioners Study Club International, Rome, Italy, Sept. 12-15. Dr. John O'Connell, 10300 Lackland Road, St. Louis 14, Mo., U. S. A., President.

International Anesthesia Research Society, London, England, Sept. 3-7. Mr. R. W. Cope, University College Hospital, London W.C.1, England.

International Association of Allergists, Zurich, Switzerland, Sept. 23-29. Prof. A. S. Grumbach, Hygiene Institut der Universitaet Zurich, Gloriastr. 32, Zurich, Switzerland.

International Congress of Anesthesiology, Nursing School of the Salpiettre, 47 Boul de l'Hospital, Paris, France, Sept. 20-22. 12 rue de Seine, Paris 6^e, France, Secretariat.

International Congress on Entomology, Amsterdam, Holland, Aug. 17-24. Dr. J. de Wilde, 136 Rapenburgerstraat, Amsterdam, Secretary.

International Congress on Industrial Medicine, Instituto Superior Técnico, Lisbon, Portugal, Sept. 9-15. Dr. Luis Guerreiro, Instituto Nacional do Trabalho e Previdência, Praça do Comercio, Lisbon, Secretary General.

International Congress on Mental Health, Mexico City, Mexico, Dec. 11-19. Mrs. Grace E. O'Neill, Division of World Affairs, National Association on Mental Health, 1790 Broadway, New York 19, N. Y.

International Congress of Physical Medicine, London, England, July 14-19. Dr. A. C. Boyle, 45, Lincoln's Inn Fields, London, W.C.2, England, Honorary Secretary.

International Gerontological Congress, Hotel Jefferson, St. Louis, Mo., U. S. A., Sept. 9-14. Dr. John E. Kirk, 5600 Arsenal Street, St. Louis 9, Mo., Chairman, Program Committee.

International Poliomyelitis Congress, Copenhagen, Denmark, Sept. 3-7. Prof. Dr. Niels Bohr, Statens Seruminstitut, 80 Amager Blvd., Copenhagen S., Denmark, President.

International Society of Surgery, Paris, France, Sept. 24-29. Dr. L. Dejardin, 141, rue Belliard, Brussels, Belgium, Secretary General.

International Society for the Welfare of Cripples, Fifth World Congress, Stockholm, Sweden, Sept. 9-14. Mr. Donald V. Wilson, 54 E. 64th St., New York 21, N. Y., U. S. A., Executive Director.

Pan Pacific Surgical Association Congress, Honolulu, Hawaii, Nov. 7-19. Dr. Forrest J. Pinkerton, Suite 7, Young Bldg., Honolulu, Hawaii, President.

World Confederation for Physicial Therapy, Copenhagen, Denmark, Sept. 7-8.

World Medical Association, Stockholm, Sweden, Sept. 15-21. Dr. Louis H. Bauer, 2 E. 103d St., New York 29, N. Y., U. S. A., Secretary General.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 24-26, 1952. Sec., Dr. D. G. Gill, 537 Dexter Ave., Montgomery 4.

Arkansas:* *Regular.* Little Rock, Nov. 8-9. Sec., Dr. Joe Verser, Harrisburg.

California: *Written.* San Francisco, Aug. 20-23. *Oral.* Los Angeles, August 18. *Oral and Clinical Examination for Foreign Medical School Graduates.* Los Angeles, August 19. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento 14.

Colorado:* *Reciprocity.* Denver, Oct. 9. Final date for filing application is Sept. 24. Ex. Sec., Mrs. Beulah H. Hudgens, 831 Republic Bldg., Denver 2.

Georgia: Atlanta, June. August, Oct. 9-11. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

Guam: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Ex. Sec., Dr. John Y. Battenfield, Agana.

Illinois: Chicago, Oct. 9-11. Superintendent of Registration, Mr. Charles F. Kervin, Capitol Building, Springfield.

Indiana: Indianapolis, June 1952. Sec., Dr. Paul R. Tindall, 1138 K of P Bldg., Indianapolis 4.

Kansas: Topeka, Dec. 12-13. Sec., Dr. O. W. Davidson, 772 New Brotherhood Bldg., Kansas City.

Kentucky: *Examination.* Louisville, Dec. 11-13. Sec., Dr. Bruce Underwood, 620 S. 3rd St., Louisville.

Maryland: *Examination.* Baltimore, Dec. 11-14. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore.

Michigan:* *Examination.* Lansing, Oct. 10-12. Sec., Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing.

Minnesota: * Minneapolis, Oct. 16-18. Sec., Dr. Julian F. DuBois, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Reciprocity.* Jackson, December. Asst. Sec., Dr. R. N. Whitfield, Old Capitol Bldg., Jackson.

New Hampshire: Concord, Sept. 12-13. Sec., Dr. John Samuel Wheeler, Room 107 State House, Concord.

New Jersey: *Examination.* Trenton, Oct. 16-19. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New Mexico:* Santa Fe, Oct. 8-9. Sec., Dr. Charles J. McGoey, Coronado Bldg., Santa Fe.

New York: *Examination.* Albany, Buffalo, New York and Syracuse, Oct. 31-Nov. 3. Sec., Dr. Jacob L. Lochner, Jr., 23 S. Pearl St., Albany.

North Carolina: Asheville, Oct. 7-8. Sec., Dr. Joseph J. Combs, Professional Bldg., Raleigh.

Ohio: *Examination.* Columbus, December. *Reciprocity.* Columbus, Oct. 2. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

Oregon:* *Reciprocity.* Portland, Oct. 12-13. Ex. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland.

Puerto Rico: *Examination.* Santurce, Sept. 4-7. Sec., Mr. Luis Cueto Coll, Box 3717, Santurce.

South Carolina: *Reciprocity.* Columbia, Sept. 10 and Oct. 1. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

South Dakota:* *Examination.* Sioux Falls, Jan. 15-16. Ex. Sec., Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Virgin Islands: Charlotte Amalie, Nov. 7-8. Sec., Dr. Earle M. Rice, St. Thomas.

Wyoming: *Examination.* Cheyenne, Oct. 1. Sec., Dr. Franklin D. Yoder, State Capitol, Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arizona: *Examination.* Tucson, Sept. 18. Sec., Mr. Francis A. Roy, 423 Liberal Arts Bldg., University of Arizona, Tucson.

Connecticut: *Examination.* New Haven, Oct. 13. Exec. Asst., Miss Mary G. Reynolds, State Board of Healing Arts, 110 Whitney Avenue, New Haven 10.

District of Columbia: *Examination.* Washington, Oct. 22-23. Sec., Dr. Daniel L. Seckinger, 4130 E. Municipal Bldg., Washington.

Michigan: Detroit and Ann Arbor, Oct. 12-13. *Examination.* Sec., Miss Eloise LeBeau, 501 W. Michigan Ave., Lansing 15.

Minnesota: *Examination.* Minneapolis, Oct. 2-3. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis.

Nebraska: *Examination.* Omaha, Oct. 2-3. Director, Bureau of Examining Boards, Mr. Oscar F. Humble, Room 1009, State Capitol Bldg., Lincoln 9.

Oklahoma: *Oklahoma City, Sept. 14. Sec.,* Dr. Frank C. Gallaher, 813 Braniff Bldg., Oklahoma City 4.

Oregon: *Examination. Portland, Sept. 8 and Dec. 1. Sec., Dr.* Charles D. Byrne, State Board of Higher Education, University of Oregon, Eugene.

South Dakota: *Examination.* Vermillion, Dec. 7-8. Sec., Dr. Gregg M. Evans, 310 E. 15th St., Yankton.

Texas: *Examination:* Austin, October. Chief Clerk, Mr. B. H. Kirk, 306 Nalle Bldg., Austin.

Wisconsin: *Examination.* Madison, Sept. 22. Sec., Mr. W. H. Barber, Ripon College, Ripon.

---

* Basic Science Certificate required.

DEATHS

MacNider, William de Berniere ⊕ Chapel Hill, N. C.; born in Chapel Hill June 25, 1881; University of North Carolina School of Medicine, Chapel Hill, 1903; Kenan research professor of pharmacology, emeritus, at his alma mater, which he had joined in 1905 as Kenan professor of pharmacology, becoming Kenan research professor of pharmacology in 1920, and serving as dean from 1937 to 1940; the William B. MacNider Award was established at the school in 1951 for public commendation of a sophomore medical student possessing the traits of character typified by Dr. MacNider during his 50 years as teacher and physician in the university; at various times special lecturer at Columbia University in New York, George Washington University School of Medicine, Washington, D. C., Medical College of Virginia, Richmond, Mayo Foundation, Rochester, Minn., and The Duke University School of Medicine, Durham, N. C.; formerly Harvey Society lecturer; consultant on gerontology, National Institutes of Health, Bethesda, Md.; chairman, Section on Pharmacology and Therapeutics of the American Medical Association, 1926-1927; member of the National Board of Medical Examiners and chairman of the examination committee, member of the National Research Council committee on nutritional aspects of ageing, the committee on cellular physiology, executive committee of the medical division; chairman of the American Division of the International Club for Research on Ageing; fellow of the American Association for the Advancement of Science, American Academy of Arts and Sciences, and the American College of Physicians; member of the American Society for Pharmacology and Experimental Therapeutics (president from 1932 to 1934, and member of the council), president of the Medical Society of the State of North Carolina (1925-1926), member of the American Physiological Society, American Association of Pathologists and Bacteriologists, American Association of Biological Chemists, Society of Experimental Biology and Medicine (president 1941-1942), American Association of University Professors, American Society for Experimental Pathology, Association of American Physicians, American Society of Anethetists, National Anaesthesia Research Society and member of the research committee, International Anaesthesia Research Society (president 1934-1935), American Association for the History of Medicine, North Carolina Academy of Science, National Academy of Sciences, New York Academy of Sciences, American Society of Naturalists, American Philosophical Society, and the Harvey Society; honorary member of the Pathological Society of Great Britain and Ireland; associate foreign member of the British Physiological Society; chairman of the council of the Gerontological Society; member of Sigma Xi, Sigmu Nu, Phi Beta Kappa, and Alpha Omega Alpha; was awarded the George M. Kober Medal in 1941 by the Association of American Physicians for research on injury to tissue cells, the New York Academy of Medicine's Edward M. Gibbs Memorial Prize in 1931; two years later was presented with the Southern Medical Association research medal; on the editorial board of the *Quarterly Journal of Studies on Alcohol;* contributor of articles to medical and biological journals; received the honorary degrees of doctor of science from the Medical College of Virginia in 1933 and doctor of laws from Davidson College in 1934; on the honorary staff of Watts Hospital in Durham, where he died May 31, aged 70, of congestive heart disease.

Morrison, Richard John, Santa Monica, Calif.; born in Glasgow, Scotland, June 22, 1880; Loyola University School of Medicine, Chicago, 1918; member of the American Medical Association; past president of Santa Monica Medical Society; president of the Marion Davies Child Guidance Clinic; chairman of the Santa Monica Welfare Clinic staff; served on the staffs of the Los Angeles County Hospital in Los Angeles and Santa Monica Hospital; past president of the Lions Club; served with the Salvation Army in Java two years during his early medical career; died May 28, aged 70, of coronary occlusion.

Maybaum, Jacob Louis ⊕ New York; Cornell University Medical College, New York, 1905; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology, American Laryngological, Rhinological and Otological Society, and the American Otological Society; fellow of the American College of Surgeons; consulting otologist, Mount Sinai Hospital, where he died May 31, aged 67, of congestive heart failure.

Morrow, Roy Darlington ⊕ Connersville, Ind.; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1907; past president of the Fayette-Franklin Counties Medical Society; served during World War I; on the staff of Fayette Memorial Hospital; died May 30, aged 67, of coronary occlusion.

Potter, La Forest, Haverford, Pa.; Boston University School of Medicine, 1884; died in St. Agnes Hospital, Philadelphia, recently, aged 85, of carcinoma of the esophagus.

Richardson, Elbert Leech, Louisville, Miss.; University of Nashville (Tenn.) Medical Department, 1907; member of the American Medical Association; for many years county health officer; past president of the East Mississippi Medical Association; died May 26, aged 69.

Rosamond, John Stribling, West, Miss.; Memphis (Tenn.) Hospital Medical College, 1901; member of the American Medical Association; medical examiner for Selective Service during World War I; for many years president of the county board of education, county health officer, and local surgeon for the Illinois Central Railroad; affiliated with Holmes County Community Hospital in Lexington and the District Two Community Hospital in Durant; died May 29, aged 77, of injuries received in an automobile accident.

Smith, Charles Edgar, Beloit, Wis.; Northwestern University Medical School, Chicago, 1901; past president of the hospital staff, Beloit Hospital; died May 21, aged 78, of coronary thrombosis and arteriosclerotic heart disease.

Southworth, Hamilton Munn, Owensburg, Ind.; Albany (N. Y.) Medical College, 1905; served during World War I; died May 26, aged 70, of cerebral hemorrhage.

Stocks, John Carter, Bountiful, Utah; Northwestern University Medical School, Chicago, 1911; member of the American Medical Association; formerly mayor of Bountiful and city councilman; died in a hospital in Ogden May 28, aged 72, of coronary occlusion.

Strong, Sneed, Dallas, Texas; Missouri Medical College, St. Louis, 1891; served during World War I; formerly affiliated with the Veterans Administration; died in the Veterans Administration Hospital, Waco, May 12, aged 86, of arteriosclerosis.

Waldrep, Archie C., Red Bay, Ala.; University of Louisville (Ky.) Medical Department, 1893; member of the American Medical Association; died May 26, aged 82, of coronary thrombosis.

Walters, John K., Mooresburg, Tenn. (licensed in Tennessee in 1892); died in East Tennessee Baptist Hospital, Knoxville, May 25, aged 86, of coronary thrombosis.

Whitacre, John Clifford ⊕ St. Paul; University of Minnesota College of Medicine and Surgery, Minneapolis, 1901; died May 28, aged 74, of coronary thrombosis.

Wight, William G. ⊕ Yale, Mich.; Trinity Medical College, Toronto, Canada, 1890; served as mayor of Yale and as president of the Yale Bank; affiliated with Yale Hospital and the Port Huron (Mich.) Hospital; died in Women's Hospital, Detroit, May 28, aged 83, of myocardial infarction.

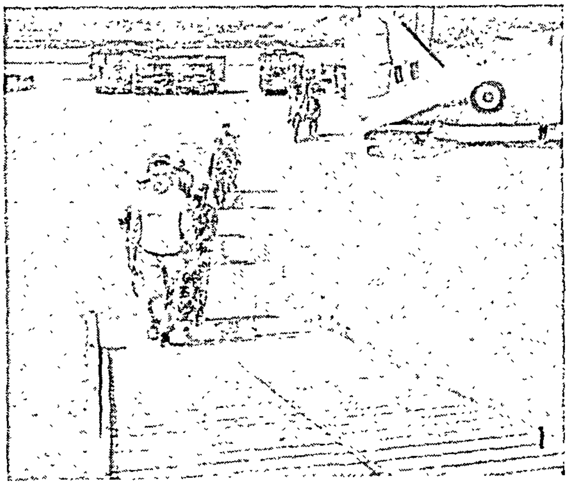
Wiley, Edwin Hardin ⊕ Los Angeles; Northwestern University Medical School, Chicago, 1901; fellow of the American College of Surgeons; on the consulting staff of St. Joseph's Hospital in Burbank, Calif., and on the staff of California Hospital, where he died May 28, aged 73, of carcinoma of the pancreas with metastases.

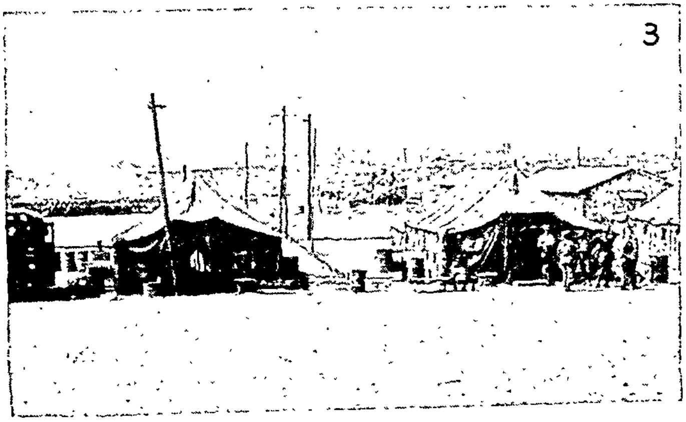
⊕ Indicates Fellow of the American Medical Association.

GOVERNMENT SERVICES

AIR EVACUATION OF PATIENTS IN KOREA

Korea (Fig. 1).—This is the beginning of an Air Force medical air evacuation. These casualties on litters from Korea will be flown to Japan for screening. The patients are being carried aboard a Douglas C-54 "Skymaster" of the USAF Troop Carrier Command.



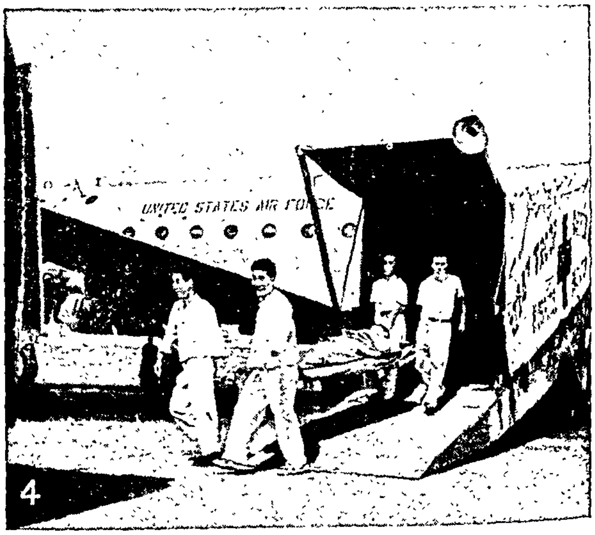


Tachikawa, Japan (Fig. 2).—Just in from an air evacuation flight from Korea, a flight nurse and a medical technician carry their medical gear from the C-54 Douglas "Skymaster" that acted as a flying hospital. Combat casualties, picked up at a Korean airstrip, have been already unloaded into ambulances and are on their way to service hospitals for treatment and screening.

Korea (Fig. 3).—This hospital on the edge of an operational airstrip is 30 minutes from the front lines. Medical technicians are readying combat casualties for medical air evacuation flights to Japan, the first leg of the air evacuation trans-Pacific crossing of the Pacific Airlift.

Tachikawa, Japan (Fig. 4).—Japanese civilian employees carry a Korean combat casualty from an Air Force C-54 Douglas "Skymaster" to a waiting ambulance for hospitalization. Air evacuation of wounded has been a major development of the Korean conflict.

Korea (Fig. 5).—The combat casualties start home by air from a dusty Korean airstrip. Medical technicians like these checking litter straps in this Air Force C-54 "Skymaster" transport, will tend the wounded through their flight to Japan and later, on the Pacific Airlift, to Continental United States.



ARMY

Malaria in Veterans Who Have Served in Korea.[1]—There are now returning from Korea many members of the Armed Forces who, while in combat, were exposed to the disease hazards of that country. The most common diseases encountered there have been bacillary dysentery, malaria, typhoid fever, typhus fever, infectious hepatitis, Japanese B encephalitis, and smallpox. By means of sanitary measures and specific immunization, Allied troops have been kept almost free of typhoid fever, typhus fever, and smallpox. Cases of dysentery, hepatitis, and encephalitis have been relatively few in number; current control measures are reasonably effective in preventing the importation of these diseases into the United States by returning troops, and research is directed toward improving preventive measures in order to eliminate even the few infections which do occur among men operating in the endemic area. Malaria, therefore, of these diseases, is one most likely to occur among veterans who have returned to the United States.

For the control of malaria, suppressive therapy with chloroquine is employed between April and October by all ground and air force personnel stationed in Korea. This is supplemented by mosquito control measures wherever possible, but the possibilities for individual exposure are greater in forward combat areas. Unavoidably, a certain number of men are bitten by infected mosquitoes, and the primary attack of malaria is usually suppressed by chloroquine therapy at that time. Since the predominant type of malarial parasite in Korea is a Temperate Zone variety of Plasmodium vivax which has a characteristically long latent period, the delayed primary attack may occur from 250 to 300 days after the infection, particularly if the individual was on suppressive therapy at the time of infection. Thus their attacks are usually seen in the late spring and early summer. For instance, among Army troops stationed in the United States, six malaria cases were reported in January of this year, eight cases in February, 24 in March, 74 in April, 309 in May, and 939 in June. Almost without exception, these patients contracted their infection in Korea. The Navy and Air Force have had comparable experiences, although of lesser magnitudes. A large number of cases may be expected in July with a diminution occurring in August and September, and another wave of attacks will probably occur next spring. Since it is neither desirable nor feasible to continue suppressive measures indefinitely and since there are no practical laboratory procedures for screening large numbers of men in order to determine infected individuals in advance of the primary attack, the Armed Services are investigating the possibility of using a new, relatively nontoxic, antimalarial compound for treating all men returning from Korea.

The treatment of cases which occur within the military service has constituted no particular problem. The cases have responded well to either chloroquine alone or chloroquine plus quinine. Although chloroquine does not prevent the occurrence of relapses of vivax infections, its administration is followed by a longer interval of freedom from attack than is observed with quinacrine (atabrine®) hydrochloride or quinine. It causes fewer reactions than other available drugs. The most frequent reaction is pruritus without rash, particularly of the palms, which occurs in about 10% of treated patients. Mild anorexia, nausea, and vertigo seldom justify discontinuance of the drug.

Chloroquine is available as chloroquine diphosphate, 0.5 gm. tablets (equivalent to 0.3 gm. base). The usual schedule used in military hospitals consists of two 0.5 gm. tablets initially followed by a single tablet after an interval of eight hours. Subsequently, single 0.5 gm. doses are given on each of the following two or three days. This schedule may be combined with quinine sulfate, 0.3 gm. orally three times a day, but ordinarily chloroquine alone is sufficient. In an endemic area, suppressive doses of chloroquine diphosphate, 0.5 gm., should be given weekly, beginning one week after the cessation of treatment and continued until four weeks after the last possible exposure.

If it were not for the fact that soldiers, sailors, and airmen occasionally have leave and many are now eligible for separation from military service, the delayed primary attacks and relapses of malaria that occur among men infected in Korea would all be treated in military hospitals. However, attacks do occur when individuals are absent from their military post, and as a result of the stepped-up separation program an increasing number will be experienced in civilian medical practice. It may be expected that the attacks will be diffusely scattered. Hence, members of the medical profession can expect to see some malaria cases among patients who are veterans of Korea.

In general, these cases of malaria are not expected to reestablish malarial infection in this country to any appreciable degree. Through cooperative efforts of the Federal, state, and local health authorities, and the practicing physicians, malaria has been almost eradicated in the United States. Control measures are now concentrated on the individual blood-positive cases. Thus, the success of the national program depends on early diagnosis and prompt reporting of all cases to appropriate health authorities. Human infection during the latent period generally is not communicable to mosquitoes. Patients with acute or chronic malaria are most infectious for mosquitoes. This period of communicability can be materially shortened by adequate medical treatment. Screening and residual insecticides should be utilized in the environment of each recognized case.

Army Postgraduate Program Extended.—A new series of postgraduate short courses for armed forces medical officers will considerably extend the Army's graduate professional education program, according to the Office of the Army Surgeon General. The new program is in keeping with the Army Career Management Plan, which provides a continuance of professional education throughout the military career of all Medical Corps and Dental Corps officers of the Army Medical Service.

A total of 18 courses will be given at five Army hospitals, the Armed Forces Institute of Pathology, and the Medical Service Graduate School, Washington, D. C., during the last six months of this year. Two courses of internal medicine are included. Other courses will be given in the second half of fiscal year 1952. (Naval and Air Force medical officers have been invited to attend these courses.)

The first of the two internal medicine courses, "Present Trends in Internal Medicine," will be given at Walter Reed Army Hospital, Washington, D. C., Oct. 8-12. Attendance will be limited to personnel from the First, Second, and Third Army Areas and the Military District of Washington. The second of the two courses, "Recent Advances in Internal Medicine," will be held at Letterman Army Hospital, San Francisco, Nov. 5-9. Attendance will be limited to personnel from the Fourth, Fifth, and Sixth Army Areas. Both courses will utilize lectures, conferences, round table discussions, and clinics.

Medical officers on active duty will be given priority in the allotment of spaces. Applications from medical officers on active duty will be forwarded through channels to: The Office of The Surgeon General, Department of the Army, Attention: Personnel Division, Washington 25, D. C. Applications from Air Force and Naval medical officers should be forwarded through regular channels. Applications from medical officers not on active duty and civilian physicians should be forwarded through channels to the commander of the installation offering the course. The commander will select those to attend on a space available basis. Army medical officers enrolled in the residency training program may attend these courses only if they are given at a hospital where the resident is being trained.

DEPARTMENT OF DEFENSE

August Induction of Medical Officers Delayed.—The planned induction under Selective Service of 333 Priority I medical officers scheduled during the month of August has been delayed temporarily at the request of the Department of Defense. The request was based entirely on the increased volunteer rate and does not represent a reduction in requirement for medical officers. Whether or not all of the doctors whose induction will be delayed during August will be called during September is dependent on the volunteer rate during the next few weeks. No reduction is anticipated for the call of 152 Priority I doctors scheduled to be inducted during September.

---

[1] Released by the Office of the Surgeon General, Department of the Army, in cooperation with the Public Health Service; the Bureau of Medicine and Surgery, Department of the Navy; and the Office of the Surgeon General, Department of the Air Force.

FOREIGN LETTERS

SWEDEN

Blood Transfusion Service in Wartime.—At a meeting in April, 1951, devoted to a discussion of wartime problems, Dr. B. Vahlquist of Uppsala and Dr. O. Wilander of Ørebro dealt with the preparations for providing Sweden with a blood transfusion service capable of meeting wartime casualties. Some of their observations were based on experiences abroad. The French, for example, have calculated as the result of experiences in World War II that some 40 L. of blood must be provided for every hundred combatants. In 1949 there were some 30,000 blood donors available in Sweden, or 0.4% of the population. This is a much lower rate than that which existed in England in 1941, when there were some 900,000 donors available. Yet even the English did not have an overabundance of donors. What makes the situation worse, more than half the Swedish donors are at the present time men liable to be called into military service.

In recent months the Swedish Red Cross, in conjunction with the Swedish Army Medical Service, has conducted a campaign for recruiting donors in the county of Uppsala. Special attention has been paid to prospective donors among women between the ages of 18 and 50. Some 1,850 persons have been medically examined and tested for blood grouping. Among them were some 250 Rh-negative persons. Though this campaign was conducted with civil defense in view, results should prove of great value also in time of peace. The Swedish military authorities have organized the wartime blood transfusion centers so that about one-third of them are mobile, ready to take up work at new centers or to supplement stationary centers with personnel and equipment. It is realized that, in an emergency and when the blood supply is inadequate, it may be necessary to resort to substitutes, such as plasma and gelatin or saline solutions. It may also be necessary to relax some of the precautionary measures taken in peacetime. The suggestion that blood transfusion services should deal only with O-donors as universal donors has not found favor, as it would reduce the total number of donors by about 50%. Even in an emergency, particularly in wartime, one should not dispense with testing blood for syphilis.

Swedish Diabetes Association.—Ever since the successful application of the discovery of insulin, diabetics have increased in such numbers that effective cooperation among them has been called for with growing insistence. The local associations of diabetics established several years ago have combined in a central organization devoted to their interests. In 1943, an official investigation of diabetes in Sweden was started; in the autumn of 1948, this investigation culminated in a report in which a careful analysis of the diabetes situation formed the basis of certain definite plans for the future. In the autumn of 1949, the various diabetes associations were fused into the central Swedish Diabetes Association, charged with the task of research and treatment. Approximately half the members of the governing body of this association are doctors; among them were two, Prof. Hjalmar Holmgren and Dr. John Byttner, who recently died. These two deaths meant a serious loss to the association, for Prof. Holmgren was engaged on important research into disturbances of carbohydrate metabolism and the rhythmic activities of the liver with special reference to diabetes, and Dr. Byttner had taken an active part in the commission of inquiry between 1943 and 1948. He was engaged, at the time of his death, on plans for a special diabetes hospital, a center for research, teaching, and treatment.

These plans have now materialized in the conversion of a small private hospital into a center of research and treatment administered by the association. This center (Frejgatan 32, Stockholm) will begin with 16 beds for diabetics and will be in charge of Dr. Jakob Möllerström, who worked for many years with Prof. Holmgren. The clinical material available at this center will be closely studied with reference to such problems as those related to the so-called tertiary stage of diabetes, i. e., the changes to be observed in the eyes, kidneys, and vascular and nervous systems in diabetes of long standing. Doctors throughout Sweden have been invited to make use of and support this center.

Experiences of the Swedish Red Cross Hospital in Korea.—The Swedish Red Cross Hospital Unit which went to Korea in the fall of 1950, and which was stationed at Pusan, gained much valuable experience during the winter of 1950-1951. In a recent lecture in Stockholm about these experiences, Dr. G. Rundberg gave an account of the many precautions taken to combat all the evils of modern warfare in an uncivilized country. The members of the unit were inoculated against smallpox, typhus, typhoid, paratyphoid, cholera, tetanus, influenza, and, in a few cases, yellow fever. Inoculation with tetanus toxoid was so effective that no case of tetanus was observed among the United Nations' troops, whereas there were several such cases among the wounded prisoners of war admitted to the Swedish Hospital. The mortality was alarmingly high, despite treatment. Only one case of smallpox was admitted to hospital; it did not give rise to any secondary cases, presumably because of the immunity of the contacts. Up to February, 1951, there were 34 cases of typhus in a camp in which there were some 110,000 prisoners of war, but only in a few of these cases did the infection begin after admission to the camp. Though inoculation against typhus must not be under-rated, the most effective method of treating it seemed to be breaking the infection cycle by killing lice. Some seven tons of DDT were used as a spray every week.

Malaria caused by Plasmodium vivax was diagnosed in three cases in the hospital. Chloroquine phosphate appeared to be superior to quinacrine hydrochloride with regard to treatment and prophylaxis. As a prophylactic, chloroquine was given in tablet form only once a week. Many of the North Koreans treated in the hospital harbored ascarides. Dr. Rundberg stated that his American colleagues in a prisoner of war hospital had come to the conclusion that 90 to 100% of the North Koreans harbor these worms. The hospital was spared cases of rabies and plague, but the arrival of the latter was feared when the Chinese joined the North Koreans. During January and February, the venereal disease rate was high, with some 200 to 250 new cases daily. Prostitution being regarded as a legitimate occupation in Korea, and the number of prostitutes in Pusan alone being estimated at between 7,000 and 10,000, provision had to be made for care of the prostitutes as well as their clients

Death of Dr. Gunnar Nilson.—Dr. Gunnar Nilson was born on Sept. 28, 1872, in Uppsala, and died on March 28, 1951. He had for long been a striking figurehead in the Swedish medical world. The son of Prof. Lars Fredrik Nilson, he was educated in Uppsala and Stockholm, qualifying as a doctor in 1895 in the former town. He took his degree of doctor of medicine at the University of Lund in 1911, his subject being varicocele and its operative treatment. As early as 1898, he was attached to the Swedish Navy; in 1917, he was put at the head of the Swedish Naval Medical Service. He held this appointment till 1937, when he reached the age limit and retired. During the more than 20 years he was at the head of this service, Nilson's initiative and driving force were largely responsible for the reforms introduced. He was a clever and careful operator, and a good organizer and administrator. His personality was forceful, and he combined with it irresistible charm. With his patrician features and bearing, and because of the similarity of his name to that of England's great naval hero, he came to be known with affectionate jocularity by his colleagues as "The Sea Lord." He became a member of the Swedish Medical Society in 1900. From 1919 to 1940 he acted as secretary of the society as well as editor for its transactions. Much of his literary work was concerned with the history of medicine; in 1945, he published a volume on "Famous Swedish Doctors." In 1947, he published the "History of the Swedish Medical Society from 1908 to 1938." His latter years were disturbed by frequent small cerebral hemorrhages.

The items in these letters are contributed by regular correspondents in the various foreign countries.

SPAIN

Public Health Meeting.—The third Public Health Meeting was held in Madrid in April, 1951. The first and second meetings were held in 1943 and 1947, respectively. Dr. A. Crespo Alvarez and collaborators spoke on the use of antibiotics in sanitary campaigns, P. González and collaborators on modern trends in public health, and G. Clavero on virus diseases. Prof. G. Ramon (Paris) lectured on vaccination against diphtheria with diphtheritic antitoxin and vaccination against tetanus and associated vaccinations. Prof. Vogel (Hamburg) lectured on immunity in bilharziasis.

International Urology Forum.—The third international forum of urologic lectures was recently held at the urologic clinic of the Faculty of Medicine of the University of Madrid. Prof. A. de la Peña is the director of the clinic. Lectures were given by Dr. F. Orts Llorca, Faculty of Medicine of Cádiz; Drs. Sanz Ibañez, J. M. Corrales, Gay Prieto, and Vallejo Najera, Faculty of Medicine of Madrid; Dr. L. Caporale, Faculty of Medicine of Turin; Dr. D. Band, University of Edinburgh; Dr. C. de Moura, Faculty of Medicine of Lisbon, and Dr. V. Carulla, Faculty of Medicine of Barcelona.

For the first time since World War II, a group of internationally known professors of urology of faculties of medicine of Homburg-Sear, Diesseldorf, Erlanger, Koeln-Merheim, and Aschen have come to the Faculty of Medicine of Madrid, thus reestablishing cordial relations between German and Spanish urologists. They came to Spain on the invitation issued to the German Society of Urology. Dr. Boeminghaus, president of the German society, headed the group. Their lectures were as follows: Prof. Alken, renal vasography; Prof. Boeminghaus, trans-sacral cystectomy; Prof. Heuschi, chemotherapy of cancer of the urinary bladder; Prof. Tiermann, trans-sacral resection of hypogastric nerves, and Prof. Koch, lithogenesis and renal crisis.

Personals.—Dr. F. Grande Covián, having passed the examination, was recently appointed to the chair of physiology of the Faculty of Medicine of Zaragoza. Dr. Grande Covián collaborated with Prof. P. Hoffmann in Freiburg in 1929 on work on the physiology of the spinal reflexes. Later, he worked with Prof. S. Ochoa and Prof. J. Negrin in the Faculty of Medicine of Madrid on muscle chemistry. In 1932 and 1933, he worked in Copenhagen with Prof. Krogh on physiology of muscular exercise. In 1933, he worked in Lund with Prof. Thunberg on dehydrogenases of fatty acids. In 1934, he worked at the University College of London with Prof. L. Evans on metabolism of the heart. From 1936 to 1939, during the civil war in Spain, he was the assistant director of the Institute of Nutrition. He studied diseases of nutrition and the role of nicotinic acid in the prevention of pellagra. He found that pellagra may develop even in persons ingesting sufficient nicotinic acid. He proved that the neurologic symptoms are independent of other symptoms that appear in patients with pellagra and pointed out that the neurologic changes are not due to a deficiency in vitamin B_1. In 1941, he started a study on nutrition in Madrid for the Rockefeller Foundation, with emphasis on the effects of poor nutrition on physical development of children. From 1942 to 1944, he studied the vitamin content of Spanish food and the intermediary metabolism of carbohydrates. From 1944 to 1949, he conducted a large number of experiments on alloxan diabetes. In 1949, he was invited to work in the biochemistry laboratory of the Neuropsychiatric Research Center in Cardiff with Prof. Richter with a scholarship from the British Council for studies on the interchange of phosphorus in nerves and the use of chromatography in studying the metabolism of amino acids in the brain. Dr. F. Grande Covián is a member of the Physiological Society, the Biochemical Society, and the Nutrition Society of England, of the Danske Biologiske Selskabet of Copenhagen, and of the Sociedad Portuguesa de Biologia. He has been a constant collaborator of Prof. C. Jiménez Diaz, director of the Instituto de Investigaciones Médicas.

Dr. L. Cifuentes Delatte successfully completed an examination for the chair of urology in the Hospital de la Princesa in Madrid. Dr. Cifuentes Delatte was a disciple of his father, Prof. P. Cifuentes Díaz and of Prof. C. Jiménez Díaz of Madrid. In 1933, he worked in Berlin with Prof. A. V. Lichtenberg. In 1946, he studied transureteral resection in the United States under Prof. Nesbit of Michigan and Alcock and Flocks of Iowa. His article on epithelium of vaginal type in the female trigone was published in America. The existence of these islands of vaginal epithelium was confirmed by Hedberg of Sweden and by Vokaer of Belgium. He wrote a book on "Cystitis and Cystopathies."

MEXICO

Macrocytic Anemias.—During the last five years, the Hospital de Enfermedades de la Nutrición undertook the study and classification of macrocytic anemias, according to the observations made in patients from regions corresponding to the Mexican plateau (altitudes ranging between 1,600 and 2,200 meters above sea level). It was learned previously, in the same institution, that the mean corpuscular volume in normal subjects living in those areas is 80 to 105 cubic microns, which is 10 cubic microns more than values in the United States. This phenomenon was called physiological macrocytosis of the altitudes, as differentiated from the physiological polycythemia of altitudes, rarely found in Mexico.

The results obtained emphasize several facts:

1. Not a single case of pernicious anemia was found in Mexican patients, regardless of the length of the period of observation and despite the hospital's being an institution in which there is some concentration of hematological cases. Of two patients in whom the existence of pernicious anemia was suspected, one did not return to the hospital and in the other the final diagnosis was nutritional macrocytic anemia.

2. In a group of 70 patients with severe malnutrition, due exclusively to dietary deficiency, 40 had macrocytic anemia, which showed the clinical form of nutritional macrocytic anemia in 26 cases; in the other 14 the clinical picture was one of sprue. The criteria for considering one case as sprue, and not as nutritional macrocytic anemia, were based on the existence, besides the anemia, of severe diarrhea with steatorrhea, abdominal distention, flat curve of the oral glucose tolerance test, and hypocalcemia.

Achlorhydria was found in 55% of the sprue cases and in 50% of the nutritional macrocytic anemia series. Neurological alterations, which often were severe (subacute combined degeneration was observed several times), were characteristic of the nutritional macrocytic anemia patients, and absent in the sprue group.

The best therapeutic results in the macrocytic anemia patients were obtained with purified liver extracts and with vitamin B_{12}, which is at variance with the observations of other investigators.

3. In 27 cases of anemia of pregnancy, there was only one with macrocytic anemia.

4. Although anemia was frequent in a series of 111 patients with proved liver cirrhosis (an incidence of 62%), in only seven of them was it macrocytic; nutritional deficiency was accepted as the cause.

5. There were no cases of macrocytic anemia in which the disease was due to hypothyroidism or to Diphyllobothrium latum.

Poliomyelitis in Mexico City.—Until 1945, poliomyelitis was uncommon in Mexico. Since then, its incidence has been increasing; in 1950, nearly a thousand cases were observed in Mexico City (incidence in lesser cities and in the country has been lower), and the figures for the first half of 1951 seem to be higher. Several explanations have been offered for this epidemiological phenomenon, none of them absolutely satisfactory.

Poliomyelitis in Mexico City has certain peculiarities worth mentioning: 1. It occurs predominantly in children under 5 years of age. 2. The death rate has been low so far—no more than 5%. Nevertheless, in this year this proportion seems to have increased also. 3. Paralysis appears only in 15% of the cases and generally is not too severe or extensive. 4. Seasonal incidence, which parallels the warmer months, is strictly related to climatic conditions. In Mexico City, the outbreaks of the disease occurred in March or April. Federal authorities have adopted all necessary and known measures, and two weeks ago a committee with representatives of the health department, of the municipal government, and of the education ministry was created to study the implications and consequences of this disease.

CORRESPONDENCE

POLIOMYELITIS

To the Editor:—With reference to an article on "Second Attacks of Poliomyelitis" by Archibald L. Hoyne and Irving Lipton, published in The Journal of the American Medical Association of June 23, 1951, I wish to call your attention to an article published by me on poliomyelitis in *California and Western Medicine,* June, 1946. This publication was the official publication of the California Medical Association on that date.

Drs. Hoyne and Lipton state in their summary, "It is probable that this is the only reported authentic second attack with fatal outcome." Perhaps the authors of this article did not completely review the literature, but I believe that the evidence presented in my article in *California and Western Medicine,* which is enclosed, leaves little doubt that this was also a second attack of poliomyelitis with fatal outcome. I am sure that this opinion was concurred in by Dr. Harold L. Faber, who was then chief of the division of pediatrics at Stanford Medical School. In the interest of scientific accuracy, I believe that The Journal might be interested in discovering that other second attacks that were fatal have occurred.

City Health Officer,
San Jose, Calif.

HYSTERIA

To the Editor:—In the article by Drs. Purtell, Robins, and Cohen (*J.A.M.A.* **146:**902 [July 7] 1951) the point is well made that "hysteria" can be suspected clinically with as much accuracy as "organic" disease. However, I feel that the name used, "hysteria," is archaic and had best be abandoned, for the following reasons: 1. It has no precise definition in either medical or lay usage. 2. It is not a disease entity, nor can it be called a syndrome. 3. Its derivation (uterus) is misleading. 4. Other terms in current usage give a better picture of the mechanisms involved.

Psychiatric literature suffers from a confusion and profusion of terms; by its very antiquity, "hysteria" is a prime example of this.

Kew Gardens Hills, N. Y.

MORE ABOUT CLOTTING IN BIBLICAL LITERATURE

To the Editor:—Dr. Cyril E. Bousfield's comment on page 1152 of The Journal for July 21 requires further comment. Where is the evidence that Jesus was dead when speared? His companions' legs were broken—a custom based on experience to keep the crucified from reviving and walking away. A spear was thrust into His side to make sure He was dead. The fact that blood came when the skin was punctured makes it likely that He was alive. The "water" is another thing entirely. Even a small amount of blood mixed with it at any time prior to the deep puncture wound would have given the appearance of blood; hence the word water would not have been used. One must conclude that an effusion was tapped, either pericardial or pleural.

611 Anderson St.,
Bristol, Tenn.

INFORMATION ON BITES FROM REPTILES AND INSECTS

To the Editor:—I have been endeavoring to obtain statistical data on the types of poisonous reptiles and insects in the various states together with the number of persons bitten each year and the number of deaths. I am having somewhat of a difficult time because practically all states do not require reports of bites or stings of poisonous reptiles or insects. State boards of health have been very kind in replying to a questionnaire giving such meager information as they have.

I have come to the conclusion that the only way I can really get much information on the subject is by contact with medical men. Since it is impossible to write each doctor and to bear the expense of correspondence, it has seemed to me that The Journal of the American Medical Association might serve as a medium for obtaining that information. The statistical data required are as follows: 1. Number of persons treated in 1950 for poisonous reptile and insect bites (list kind of reptile or insect). 2. Number of persons treated in 1949 for poisonous reptile and insect bites (list kind of reptile or insect). 3. Number of deaths.

MEDICAL MOTION PICTURES

The Stowaway: 16 mm., black and white, sound. Part I, Disease and Personal Hygiene (TF 8-1501), 17 min. Part II, Galley Sanitation (TF 8-1502), 24 min. Part III, Food Storage (TF 8-1503), 12 min. Produced in 1949 by the U. S. Army. Procurable on loan from Army Surgeon of Army Area in which the request originates, or on purchase from United World Films, Inc., 1445 Park Ave., New York 29.

Part I, Disease and Personal Hygiene, reveals both obvious and obscure ways in which disease is spread by food-handling personnel and clearly illustrates proper sanitary precautions and remedies. The methods shown in this film will help eliminate the spread of disease caused by careless personal hygiene of food handlers.

Part II, Galley Sanitation, presents methods of sanitation observed in a ship's galley as an illustration of how food service organizations should exercise every precaution to insure all sanitary measures in preventing the spread of disease.

Part III, Food Storage, covers the careful inspection of food by the U. S. Army Veterinary Corps, the Bureau of Animal Industry and the Port Food Service Inspector prior to procurement and use aboard troop transports. It shows in detail the proper facilities for food storage and the principles used for the proper storage and preservation of food.

Part I approaches the problems of causes of contamination negatively, showing how all the rules of hygiene can be and are broken. Parts II and III are "how to do it" films in which the teaching is accomplished by positive methods. They provide motivation by the use of excellent, clearly illustrated examples of why and how to store food properly. Repetition is used very effectively as a teaching method. Although these films are primarily concerned with the training of food handlers on troop transport ships, the lessons taught are applicable to other situations. These films are highly recommended for the beginning and in-service training of all personnel engaged in or planning to engage in food handling; however, certain aspects of Part I limit its use to male audiences. The photography and sound are excellent.

Surgical Anatomy of the Inguinal Area: 16 mm., color, silent, showing time 29 min. Prepared by *Conrad J. Baumgartner, M.D., and De Vere W. McGuffin, M.D.* Produced in 1947 by Department of Visual Education, College of Medical Evangelists, 312 N. Boyle Ave., Los Angeles 33. Procurable on loan from *Davis & Geck, Inc.,* 57 Willoughby St., Brooklyn 1.

This film shows the anatomy encountered in the repair of an inguinal hernia with particular attention to the transversalis fascia and Cooper's ligament. The dissection is performed on a fresh cadaver. The anatomy of the inguinal region is unusually well presented. The relation of the transversalis fascia to the femoral sheath and the location of Cooper's ligament are beautifully demonstrated. The anatomic structures used in the repair of the inguinal hernia are much better shown than on most films on the technic of inguinal hernia repair. The film is well captioned. This is an excellent teaching film and could be recommended for use in the teaching of anatomy to first year medical students as well as for the teaching of the technic of hernia repair to third and fourth year medical students. It would also be applicable for the teaching of interns, residents, and surgeons.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Prenatal Injury: Liability for Stillbirth Following Motor Bus Accident.—The plaintiff and her husband filed suit for damages alleged to have resulted from injuries sustained by the plaintiff in a motor bus accident. From a judgment for the plaintiff, the defendant appealed to the court of appeal of Louisiana.

The motor bus, which was owned and operated by the defendant corporation, was driven into a ditch and the driver attempted to extricate it before allowing the passengers to alight. Although, in certain parts of the record, it is contended that the plaintiff was thrown to the floor of the bus, this did not occur; she caught herself on the seat ahead of her and received, as a matter of fact, only a slight jolt. At the time of the accident, however, the plaintiff was two to four months pregnant and about five and one-half months later the child with which she had been pregnant was born dead.

The major item of loss claimed by the plaintiff was based on the fact that the expected child was born dead, and the defendants contended that for such an item of loss or damage there can be no recovery, as a matter of law, regardless of the cause.

The defendant directed the court's attention to Article 28 of the Civil Code providing: "Children born dead are considered as if they had never been born or conceived." The defendants argued that since a child born dead is considered as never having been conceived, it must be concluded that nothing has been lost since there can be no loss of anything that has never existed. We can not be persuaded, said the court, that there are no circumstances under which damages should be awarded to the parents of the unborn child if the foetus, while in its mother's womb, has been so injured that it cannot be borne alive. We are certain that the redactors of our code had no such purpose in mind in enacting Article 28.

The court was referred to a discussion on the subject of "Tort Liability for Prenatal Injury" in 24 T. L. R. at page 435. The author of that article says that as a general rule "there can be no recovery for the loss of the society and prospective earnings of the child." There could, however, be a recovery for a result of an accident which might cause sterility, or which might otherwise prevent parents from having children, said the court. If, as the result of actionable negligence, a husband or wife should be so injured that either, in the future, could not expect to produce children, surely this would be taken into consideration as an item of damage. It necessarily follows that when parents are actually expecting arrival of a child, and are deprived of the fruition of that great expectation by someone's actionable negligence, they may recover from the tortfeasor for that particular loss. In the article above referred to, the author also says "although mental anguish based specifically upon the loss or death of the child is not recoverable, recovery has been allowed for the mother's mental anguish if the child is born malformed." If the mother may recover for the mental anguish caused by the fact that the child has been born malformed, said the court, it is surely illogical to hold that, under the same circumstances, the mother cannot recover where, as the result of negligence, the child is prevented from coming into existence at all. In the same article the author states that, where there is an injury to a pregnant woman "there may be recovery for the fear that harm may have resulted to the child." If this is true, surely it should follow that if that fear is realized and the child is stillborn, there should be allowed recovery for the stillbirth of the child. As a matter of fact, said the court, the author of the article concludes with a statement that, in all such cases in which it is contended that some accident has caused prenatal injuries, "the evidence to prove causal relationship should be subjected to the strictest examination." And that is our conclusion here, said the court of appeals, that as a matter of law, there may be recovery by the parents where there is actionable negligence which causes such injury to a viable foetus as to prevent its being born alive, but that there must be strict proof that the actionable negligence was the cause of the unfortunate occurrence.

The court next considered whether or not the plaintiffs introduced sufficient evidence to indicate that the stillbirth was caused by the accident. The plaintiff contended that the accident made it necessary for the plaintiff to remain in bed for a large part of the time, that she remained inactive and took no exercise, and that as a result her weight became very excessive, with the secondary result that the weight of the viable foetus became also excessive and that, as a consequence, the foetus itself grew so large that it could not be born alive. Dr. LaRocca, the attending physician, did not attribute the stillbirth directly to the accident. He said: "I did not say the trauma caused the death. I said that the oversize of the baby, and the abnormal circumstances of her pregnancy, were the cause of the death of the baby." He explained that what he meant by "abnormal" condition of her pregnancy, was the fact that the plaintiff was confined to her bed for long periods, with the result that she and the baby grew to abnormal proportions. We are of the opinion, said the court, that the overwhelming weight of medical testimony is to the effect that these factors had nothing to do with the somewhat abnormal development of the foetus. The testimony of a number of doctors indicates that no matter how much an expectant mother may eat, the foetus absorbs only so much as nature requires, and that its size does not depend at all on the quantity of food taken by the mother. These doctors also stated that the fact that the mother is required to remain in bed for several hours each day and that she is permitted to take little or no exercise does not affect the size of the foetus.

We conclude, as we have stated, that the abnormal size of the foetus was not the result of the fact that the mother herself was tremendously overweight and that she was required to remain inactive for several hours each day. In reaching this conclusion, the court continued, we have not been able to lose sight of the fact that the record strongly suggests another cause for the abnormal size of the unborn foetus. All of the doctors agree that diabetes of a mother is almost always the cause of abnormal growth of the foetus. While Dr. LaRocca stated that the plaintiff did not have true diabetes, he conceded that she had what he said was "transitory" diabetes, and the diet which he required for her was one which is recognized for diabetes. He says, too, that he took into consideration the fact that the plaintiff was much overweight and that she was confined to her bed for long periods and prescribed a diet accordingly, and he very significantly added, "If she had lived up to it her weight would have been reduced." The medical experts who testified on behalf of the defendants stated that they did not know of such disease as transitory diabetes but there can be no doubt that the overwhelming medical testimony shows conclusively that the percentage of abortions and stillbirths among diabetic women is tremendously greater than among women not so affected.

Even if it could be conceded that the size of the baby was not the result of the mother's tendency to diabetes and was not the result of the extreme overweight of the mother or of her long periods of rest, still there is no proof whatever that its size was the cause of its being stillborn. Dr. LaRocca knew of its size. He had made all necessary examinations of the mother and at the time he knew of nothing which would have prevented her from giving normal birth to a child even of that size. We cannot say how much significance should be attached to it, but we have not been able to lose sight of the fact that although the plaintiff had given birth to her first child, which was still living, she had, some five years before the present occurrence, given birth to another stillborn child, thus possibly indicating a tendency which may have been felt at this time.

Our conclusion is that at most all that can be said is that there was a sequence of events which may have led a layman to feel that the stillbirth was the result of the accident, but that the overwhelming medical testimony makes it impossible that we accept that conclusion and we have decided that no allowance should be made for the fact that the child was not born alive.

The court therefore held that the parents had a right to maintain an action for damages for the stillbirth but that they failed to prove that the stillbirth was caused by the accident. Other items of damages were, however, awarded, and the judgment in favor of the plaintiff was affirmed.—*Valence v. Louisiana Power & Light Co., 50 So. (2d) 847 (Louisiana, 1951).*

Current Research Problems Concerning Pulmonary Granulomatosis in Beryllium Workers. F. Klemperer.—p. 625.

Spontaneous Remission of Chronic Beryllium Poisoning.—Cass describes the case of a man who, in January, 1943, complained of shortness of breath, loss of weight, and general weakness. Roentgenograms of the chest led to a questionable diagnosis of sarcoid, but further inquiry revealed that in 1941 the man had worked in a fluorescent lamp factory. Later it was recognized that this man had a syndrome similar to that found in several other employees of this company and that it was probably beryllium poisoning. The patient remained disabled and acutely ill for six or seven months. Finally he began to improve. At the end of eight months he was well enough to go back to part-time work, and about one year after the onset of the illness he was able to return to full-time work. Roentgenograms of the chest still show diffuse granulomatous lesions, but the individual nodules seem smaller and more dense than formerly. Small stones were passed during several episodes of acute renal colic, and their analysis revealed beryllium, but the last time stones were passed, they showed no evidence of beryllium. The patient received medical supervision but no specific therapy. The author doubts that either corticotrophin (ACTH) or cortisone should be used for this disease over long periods as has been suggested by some. He feels that as adjuncts to other symptomatic therapy during the phase of prostration and debility, as a means of producing general systemic stimulation, their use may be justified, but there is little justification for using them simply because the roentgenograms show improvement of the pulmonary lesions. In fact, this may be a disadvantage, for the removal of the protective band of lymphocytes from the beryllium particles may result in an undesired freeing of beryllium.

Hearing Loss and Nutritional Deficiency.—Lobel cites several investigations on the value of an injectable vitamin A preparation in otosclerosis and other types of impaired hearing not amenable to the usual otolaryngologic methods of treatment, and then describes patients with hearing loss who have been treated primarily with vitamin A and other measures. He concludes that the present clinical study, like some previous ones, indicates that vitamin deficiency and hearing loss are in some manner related. Results of clinical trials with an injectable vitamin A preparation hold promise of its therapeutic value in certain types of deafness. Despite the fact that in some instances the hearing loss was not influenced, the accompanying tinnitus was greatly relieved. Further trials with vitamin A, alone or combined with other vitamins, seem definitely warranted.

Prevention of Degenerative Vascular Lesions in Diabetes Mellitus.—Studies were made of 247 patients with diabetes mellitus, 122 males and 125 females, with age of onset from 18 months to 30 yr. and with duration from 10 to 34 yr. Particular emphasis was given to the relationship between control of the diabetes mellitus and the development of degenerative lesions in the kidneys, retinas, and blood vessels. Ideal or perfect control of diabetes mellitus implies that a balanced diet has been so well utilized by an adequate insulin effect that blood and urine tests are invariably normal. When various degrees of control were plotted against the duration of diabetes and the development of calcified vessels, retinitis, and albuminuria, the following facts appeared: No patients with excellent or good control showed advanced calcification or pronounced retinitis even after periods of 20 to 34 yr. of diabetes mellitus. Diabetic nephropathy did not develop in patients with good or excellent control, even after periods of 20 to 34 yr., but did appear in 62 patients with poor or fair control, 13 of whom died during the year of this study. Four out of 103 patients with diabetes for periods of at least 20 yr. had excellent control. Three of these had no retinal lesions. Of 54 with moderate to pronounced retinitis, all but five had had fair or poor control and none had had excellent control. Of 80 patients who lived for periods of at least 20 yr. on an unmeasured diet without constant use of insulin and without constant control of glycosuria, 55 showed severe degenerative vascular lesions. Whatever the specific etiological factors causing diabetic degenerative lesions may be, it has been demonstrated that the regulation of diabetes mellitus controls these factors. Control of diabetes mellitus is thus more important than any known factor, such as duration or severity, in prevention of these degenerative complications.

Cortisone in Chronic Regional Enteritis and Chronic Ulcerative Colitis.—Three patients with chronic regional enteritis with or without involvement of the proximal colon and three patients with chronic ulcerative colitis were subjected to a therapeutic trial with cortisone. The drug was injected subcutaneously according to the following schedule: 100 mg. every eight hours for three doses, then 200 mg. every 12 hr. for two doses, and thereafter 50 mg. every 12 hr. for eight additional days. Moderate to pronounced remission of symptoms occurred in the three patients with regional enteritis and in two of the patients with ulcerative colitis. In the three patients with regional enteritis the improvement seemed to be definitely related to the cortisone; the evidence was less clear in the two patients with ulcerative colitis. In each of the five improved patients a relapse occurred within five to 73 days after cessation of treatment. The best responses were obtained in the two patients who had the lowest initial eosinophil counts. The patient with the highest eosinophil count showed no improvement. Two of the three patients who responded most dramatically were the most critically ill of the group, which suggests that the severity of the disease is one of the factors determining a good response. A trial of cortisone therapy would appear to be worth while in certain cases of regional enteritis or ulcerative colitis, particularly in critically ill patients when the situation is desperate and a long enough period of improvement is desired for the effective use of other therapeutic measures. Cortisone does not ensure cure of the disease, as a relapse may occur after administration of the drug is discontinued.

Growth and Spread of Cancer of Cervix Uteri.—Cancer of the cervix uteri may begin as carcinoma in situ, a disease that has been detected in patients whose average age is eight to 12 years younger than that of women with infiltrative cancer of the cervix. If it can be shown that carcinoma in situ is the usual precursor of infiltrative cancer, these figures would suggest that there may be a prolonged period during which incipient cancer may be detected and treated with the prospect of close to 100% cure rate. On the contrary, untreated invasive cancer of the cervix is a rapidly fatal disease. Of 171 women with cancer of the cervix seen at the New York Cancer Institute between 1930 and 1949 who had not received surgical or irradiation treatment, 58% died within one year of the onset of symptoms and 82% within two years. Four and six-tenths per cent of the women with untreated cervical cancer survived five years. Radical hysterectomy was performed on 91 women with cancer of the cervix. Microscopic examination of the parametrial tissue outside the cervix showed invasion by cancer in about half the patients, proving that parametrial involvement occurs by direct extension fairly rapidly. Only 15 (16.5%) of these 91 patients showed lymph node metastases. The nodes in the obturator fossa were the sites of metastasis in nine patients, the lymph node lying in the bifurcation of the common iliac artery ("hypogastric node") in eight patients and in the common iliac nodes in four patients. Necropsy in patients who died of cancer of the cervix revealed metastatic disease outside the pelvis in only about 50%. The commonest sites of metastasis were the periaortic and retroperitoneal nodes, the liver, the lung, and the vertebral column. The commonest cause of death in cancer of cervix uteri is either ureteral obstruction or infection of the urinary tract associated with it. Operative relief of such obstruction is of doubtful value, unless there is some promising method of curing the primary tumor.

Irradiation Treatment of Cancer of the Cervix Uteri.—A questionnaire sent to the heads of the departments of gynecology of the 77 medical schools in the United States and Canada demonstrated that these physicians prefer irradiation treatment to surgical treatment of cervical cancer. This report shows the end results of a planned course of irradiation therapy in 188 patients with cervical carcinoma who had no previous treatment. They were given 50 mg. of radium element in tandem filtered by 2 mm. of brass and 3 mm. of para rubber for 1,500 mg. hr. every eight days in three applications for a total of 4,500 mg. hr. The radium dose administered to area A was 7,000 gamma roentgens and, to area B, 1,540 gamma roentgens. On the days the patient was not receiving radium therapy, she was given daily roentgen treatment to one field; 250 or 300 r was administered daily, and the total number of fields was regulated by the measurement of the patient. A total tumor dose of 3,500 to 4,000 r was given. Of the 188 patients, 43.6% are free of evidence of disease after five years. The complications associated with irradiation of the pelvis were not found to be frequent or severe enough to cause rejection of this method of therapy. The cell type of the disease in no way aided in prognostication. The response of the tumor to therapy and the extent of the disease definitely influenced the prognosis. It is therefore recognized that any pronounced progress in saving the life of patients with carcinoma of the cervix must be made through early detection of the lesion. There is no evidence that primary surgical treatment holds any advantage over irradiation therapy.

Thromboembolism in Children.—During the 12-yr. period ending June 30, 1950, thromboembolism occurred in 35 children aged 12 or less who were admitted to a large general hospital. While the over-all incidence of thromboembolism is lower in children than in adults, a higher percentage of the cases in children are fatal. The age distribution of the fatal cases in children closely followed the age distribution of all fatalities in the hospital, the highest incidence occurring in early infancy. In contrast with thrombosis in adults, major precipitating factors are essential for thrombosis to develop in children. The newborn infant is particularly susceptible to such precipitating factors as infection, dehydration, malnutrition, and circulatory stasis. Nonseptic peripheral thrombosis was rarely observed in the children reported on. Visceral thrombosis was common and frequently contributed directly to a fatal outcome. Pulmonary embolism, thrombosis, or both, were frequently observed in younger and older children. Heart disease was a significant cause of thrombosis in older children. The incidence of thrombosis in children has diminished during the period of the author's study, while the adult incidence has doubled. This improvement resulted primarily because of the control of infections previously leading to venous thrombosis in children. The incidence should be further reduced as the principles and techniques of hydration, nutrition, and control of regional and systemic infections are applied more vigorously.

Surgical Intervention in Ulcerative Colitis.—Of 770 patients with ulcerative colitis treated at the Lahey Clinic, 308 required surgical therapy. Ileostomy was the procedure most frequently performed. Because of improvement in the medical and surgical management of these patients the mortality rate for this operation has been reduced from 18.6% to 2% since 1947. An important medical advance has been the use of corticotrophin (ACTH), which brought about a remission in 21 out of 28 patients in this series. This made it unnecessary to perform ileostomy and colectomy during the acute stage, when the mortality rate is high. Early ileostomy is justified in a patient in the acute stage of the disease when remission has not occurred promptly with corticotrophin. The performance of ileostomy and its management has been improved, so that complications such as skin erosion, prolapse, and retraction of ileostomy no longer occur. Bowel hemorrhage in the acute phase of the disease is another indication for prompt ileostomy. If colectomy then becomes urgently necessary because of failure to control the bleeding from the colon, it can be undertaken with the ileostomy already established and the fecal stream sidetracked. Ileostomy and partial resection of the colon combined in one operation may elevate the mortality rate unduly and should be done only in good risk patients by surgeons with experience in these cases, and even then with extreme caution. Acute perforation has not been a common complication in the author's experience. Chronic perforation was frequently associated with obstruction and with a walled-off abscess. All closures of perforations for ulcerative colitis should be combined with ileostomy. Involvement of the joints is a definite indication for prompt ileostomy, to be followed by total colectomy and abdominosacral removal of the rectum. The same applies to multiple anal fistulas that produce induration of the perineal tissues and resultant rigid anal sphincters. Colectomy is advised for all patients who have had a permanent ileostomy established.

PAS and Resistance of Tubercle Bacilli to Streptomycin.—The studies reviewed in this paper were carried out in participation with the Veterans Administration-Army-Navy Research Program, which used paraaminosalicylic acid in combination with streptomycin. The aim was to delay streptomycin resistance by lowering of the total dosage of streptomycin and by addition of a synergistic drug. Streptomycin resistance was studied with the following therapeutic schedules: (1) streptomycin, 1 gm. daily for 42 days; (2) streptomycin, 1 gm. daily, paraaminosalicylic acid, 8 gm. daily, for 120 days; (3) streptomycin, 1 gm. daily, paraaminosalicylic acid, 15 gm. daily, for 120 days; (4) streptomycin, 1 gm. daily, paraaminosalicylic acid, 12 gm. daily, for 90 days, and (5) streptomycin, 1 gm. daily, paraaminosalicylic acid, 12 gm. daily, for 120 days. Streptomycin sensitivity tests were recorded at 60, 90, and 120 days after the start of treatment. There was a decided reduction in the number of patients showing tubercle bacilli that were resistant to streptomycin when combined therapy with paraaminosalicylic acid was employed.

Jaundice in Chronic Hepatitis.—In order to determine the significance and pathogenesis of jaundice in portal cirrhosis, Ricketts studied 28 consecutive patients, three children and 25 adults (22 males and six females) with pronounced jaundice by simultaneous clinical and histological observation and by conventional biochemical determinations. A previous history of alcoholism was detected in 13 of the 28 patients and an insidious onset of jaundice in 21. The following findings, occurring singly or in combination, were significant in the diagnosis of chronic hepatitis: collateral circulation of the abdomen, spider nevi, telangiectasis, hard or nodular liver, and varicose veins of the esophagus. Punch biopsy of the liver was the most important single diagnostic procedure used, since it served to demonstrate not only liver fibrosis but also changes of the liver parenchyma. Jaundice in patients with cirrhosis represents active parenchymatous liver disease and as such cannot be regarded as a manifestation of "compensated cirrhosis." Pathologically there were active changes of the liver parenchyma that varied considerably in type and severity. There was no relation between jaundice and the degree or type of fibrosis. Jaundice appeared as a slight, transitory, almost unnoticed episode in the course of chronic hepatitis, or most commonly it was accompanied by other symptoms and findings of liver failure, such as edema, ascites, and encephalopathy. Jaundice is to be considered a very serious sign; nine of the 28 patients died during the episode of jaundice, eight of liver failure and one of liver failure and gastrointestinal bleeding. The presence of jaundice contraindicates abdominal surgery. The importance of medical management of portal cirrhosis with jaundice is emphasized, since even patients with severe liver failure can recover clinically. Recovery is accompanied by disappearance of degenerative features, regeneration of the liver parenchyma, and pronounced improvement of parenchymal function.

Ineffectiveness of Enterogastrone in Peptic Ulcer.—Thirty-four patients, 32 men and two women with chronic peptic ulcer, were treated with enterogastrone for prolonged periods. Enterogastrone was given orally to 19 patients, of whom two were given doses of 6 gm. daily for an average of 6.5 months, five were given 8 gm. daily for an average of 11.5 months, and 12 were given 16 gm. daily for an average of 7.2 months. Intramuscular injections of 200 mg. of enterogastrone were given to 15 patients six times a week for an average of 5.5 months. Only eight of the 34 patients, with an average duration of the ulcer history of 14.2 yr., were significantly improved, as shown by decreased recurrence rate, absence of complications, or lack of need for surgery. Of these eight patients, three had received parenteral enterogastrone, four had received 16 gm. of oral enterogastrone daily, and one had received 8 gm. of oral enterogastrone daily. Twenty-six patients had an increase in recurrences, more intense symptoms, or ulcer complications such as obstruction, hemorrhage, or perforation. Eighteen patients underwent surgical treatment because of ulcer complications or intractable symptoms. Prolonged oral administration of enterogastrone in doses of 16 gm. daily or of intramuscularly administered enterogastrone did not significantly alter the rate of gastric secretion, free hydrochloric acid content of gastric juice, or pepsin content of gastric juice in the authors' patients. Gastric motility was also not altered.

Clinical Management of Peptic Ulcers in General Practice. O. R. Bowen.—p. 381.

Cardiotoxic Action of Intravenously Administered Procaine.—Electrocardiographic studies were made on 42 patients in connection with procaine infusions. A total of 257 electrocardiograms were made in connection with 263 infusions. The tracing made prior to the first infusion served as the control. In most cases procaine infusions were given daily; others received infusions on alternate days. Treatment was given until either an excellent therapeutic result was obtained or further infusions failed to improve the condition. Analysis of the electrocardiograms revealed P-wave alterations in four cases, prolongation of the P-R interval in 5 cases, a decrease in 17 cases and an increase in two cases in the QRS voltage, and a T voltage decrease in 16 cases and an increase in eight cases. Twelve patients showed no change following repeated infusions; of the others, some showed one and others several changes. In two cases the changes were sufficiently severe to justify cessation of treatment. The duration of the changes was variable and could not be correlated with their extent. In general, the changes were gone in 24 hr., but in several patients they persisted longer than three days. The following conclusions are drawn on the basis of the described observations: Intravenously administered procaine has a depressant action on both the myocardium and the conduction system. This action is beneficial in ventricular arrhythmias but does not occur in auricular arrhythmias. Intravenously administered procaine should be used with caution in persons with heart disease; electrocardiograms should be made before and during treatment.

Pituitary Necrosis and Diabetes Mellitus. E. R. Marzullo and M. B. Handelsman.—p. 537.

Irradiation of Pituitary in Malignant Exophthalmos.—The initial symptoms of "malignant" exophthalmos are usually orbital, retro-orbital, or frontal pain, burning, lacrimation, photophobia, and, less commonly, diplopia. The eyes become proptosed; the lids swell, and edema and fluid appears under the conjunctivas. Conjunctival sacs may protrude between the lids or hang down over the cheeks. When the patient loses his ability to close the eyes while asleep, exposure keratitis, corneal ulceration, panophthalmitis, surgical loss of the orbit, or death may follow. Decrease in protrusion of the eyes is rarely brought about by lowering of the basal metabolic rate when it is elevated or by the administration of desiccated thyroid when it is not. Surgical decompression of the orbit is effective in this condition, but this is a relatively formidable procedure. Roentgen therapy directed to the pituitary was used in 10 patients with malignant exophthalmos and in one patient with progressive exophthalmos. These patients were selected for treatment because their eye status became worse during an average control period of 10.7 months, during which time they were treated with desiccated thyroid. Seven of the 10 patients with malignant exophthalmos and the one patient with progressive exophthalmos had significant recession in exophthalmos. Only one of the three nonresponsive patients showed a significant increase in exophthalmos. Transient epilation resulted in all patients, and there were occasional headaches during the first few weeks after treatment. Patients who responded showed recession at an average interval of three months and maximum recession at an average interval of 12 months after roentgen irradiation.

Retropubic Prostatectomy: Modification of Millin Technique.—This is a report of Carruthers' modification of Millin's technique of prostatectomy and is based on a series of 53 consecutive prostatectomies, performed during the last two and one-half years. This modification allows better exposure, anatomic dissection, and control of bleeding, with minimal shock to the patient. It is applicable in all types of prostatic obstruction and makes this field available to the general surgeon or urologist who is not trained in the highly specialized field of transurethral resection. The gland is completely removed, and there is no tendency to stricture formation. Postoperative urethrograms show the prostatic cavity to be confluent with the urinary bladder. Nursing and hospital care are minimal and well suited to a general hospital. Confinement to bed has been shortened, with an early return to normal micturition. Sexual function has not been disturbed.

Oxygen Administration When Intratracheal Tube Fails.—Brantigan describes a new technique of emergency oxygen administration for use when an intratracheal tube slips out during anesthesia. A no. 17 intravenous needle, which is attached by rubber tubing to an oxygen tank, is inserted into the bronchus. The assistant holds the needle in place, and the operator controls the flow of oxygen. The no. 17 needle acts as a safety mechanism, since it tends to prevent an excessive flow. The escape of oxygen from the glottis aids in reinsertion of the intratracheal tube, which can be done without haste. It is suggested that the oxygen tank and sterile rubber tubing with needle attached be available in the operating room.

Cystectomy and Urinary Diversion in Carcinoma of Bladder.—Cystectomy was done for cancer of the bladder in 36 patients at two Veterans Administration hospitals, one of which was a tumor center. A total of 325 patients with carcinoma of the bladder were observed at these hospitals. In patients who underwent cystectomy an attempt at removal of cancer of the bladder had been delayed an average of three and a half years. From their study of these cases, the authors made the following conclusions: Gross hematuria may not be the first symptom of cancer of the bladder, but, since most tumors of the bladder produce blood and other cells in the urinary sediment long before gross hematuria occurs, such findings should suggest a complete urologic examination. The cystoscopist, who can view the entire bladder, can make a more accurate diagnosis of malignant change than the pathologist who examines only a bit of tissue removed transurethrally. Because of frequent errors in the study of biopsy specimens, surgical exploration of the bladder and the surrounding structures should be done before deciding on a cystectomy. At this exploratory operation the diversion of the urinary stream into the bowel or into the skin can be undertaken. Cystectomy should be used only when the degree of malignancy is no greater than grade 2 and when the cancer is confined to the lumen of the bladder. Metastases occur early and may be widespread with any degree of malignancy. Diversion of the urinary stream into the sigmoid or through the skin is the best palliative treatment. Implantation into the skin is the safest method. In this series there was a high mortality rate following cystectomy. Two patients lived four years and 11 months, and one lived five years and six months. Eight (29%) lived more than a year. One lived more than two years. The average survival was 10 months. There were local recurrences in many cases, and metastases to the bones also occurred frequently.

Substitute Bladder and Urethra.—In the treatment of certain tumors of the rectum, uterus, bladder, and prostate, in certain congenital anomalies and in conditions such as extensive vesicovaginal and rectovaginal fistulas, it may be highly desirable to divert the urinary stream above the bladder. Numerous operations have been designed, but each has limitations. In the technique described in this paper the new bladder is made from the isolated terminal ileum, cecum, and ascending colon. Bowel continuity is reestablished by ileocolostomy, and the ureters are transplanted to the new bladder. The terminal ileum is brought out to the abdomen to serve as the urethra and an indwelling catheter is left in the new bladder. Finally, the patient is taught how to catheterize himself often enough to prevent overflow leakage. This arrangement has the following advantages: (1) There is no contamination by the fecal stream. (2) The ureteral anastomoses are easily made and can be covered by peritoneum. (3) A cystoscope can be passed to the new bladder and the ureteral orifices can be dilated or otherwise treated if need be. (4) No device is needed to prevent leakage. (5) There is no limitation of radical surgery when dealing with malignant lesions. In animal experiments and in the follow-up study of human patients the authors encountered no real contraindication to this procedure.

Combined Therapy and Drug Resistance.—This study shows that the therapeutic effect of combined antibacterial agents is correlated with the inhibition of drug resistance. A total of 37 cases, including both uncomplicated urinary tract infections (e. g., cystitis, pyelonephritis, and urethritis) and those complicated by pathological changes, such as calculi, strictures, and obstructions, were studied. The patients received the following daily dosage for a total of seven days: streptomycin, 1.0 gm., intramuscularly; penicillin, 200,000 units, intramuscularly; sulfadiazine, 2.0 gm., orally. Sterile urine cultures were obtained in 16 cases, 14 of which were uncomplicated urinary tract infections. Therapy was bacteriologically unsuccessful in 21 cases, 19 of which were characterized by some complication. In these 19 cases, bacteria resistant to all three drugs regularly emerged. A study of resistant strains in the urine and feces of seven patients strongly indicated that many of the resistant strains in the urine had their origins in the fecal flora of the patient. Good clinical response was obtained in virtually all the cases in spite of persistent bacilluria. The combined drugs produced no evidence of toxicity. If combined therapy is to be of permanent value, efforts must be made to remove the cause of the obstruction or complication.

Bone Marrow in Radiation Injury.—This report deals with the use of bone marrow in animals severely injured by acute, whole body exposure to roentgen irradiation. The experimental approach was based on the fact that in this type of injury there is extensive bone marrow damage with extreme depression of hematopoiesis and on the hypothesis that this results in an unusual demand for the products of marrow metabolism. Preliminary studies of bone marrow homotransplants in rats with marrow depressed by benzene injections and by whole body roentgen irradiation suggested that the transplants would survive in a reasonably healthy condition for an approximate minimum of four weeks. In the main experiment one group of white rats exposed to 500 r total body irradiation was given one intramuscular injection of marrow and a similar group two injections of marrow three to four days apart. Another series of rats received intrahepatic marrow homotransplants following single, whole body exposures to 700 r. A control group not operated on and a special control group the hind limbs of which were two-thirds to three-fourths shielded by 1.5 cm. of lead were simultaneously studied. There was no apparent benefit in terms of survival and postirradiation total leukocyte counts in the case of the marrow-transplanted group; however, the survival of these animals, each of which experienced general anesthesia, laparotomy, and injection into the liver, was at least as good as that of the controls not operated on. The shielded group had a mean survival time 2.4 times that of both the animals with transplants and the control animals.

Primary Intestinal Anastomoses.—This and other papers in this issue pay tribute to Owen H. Wangensteen for his work in relieving gastric and intestinal distention by intubation. Intestinal intubation as introduced by Wangensteen and extended by others has reduced the morbidity and mortality rates of many diseases and procedures. Ravdin and DeMuth say that with its help bowel resection and primary anastomosis has become a safe operation in many patients. During the past five years there has been a steady increase in the number of primary anastomoses following bowel resection, regardless of location of the lesion. The control of distention is the clue to successful preparation of the bowel for primary anastomosis. The authors report results obtained in the five-year period between 1946 and 1950 inclusive in 394 patients in whom primary intestinal anastomoses accompanied by intubation and suction drainage were the sole source of decompression. Intestinal resections were done in all but 38 of the reported cases. The over-all mortality rate was 3.8%. Primary anastomosis following resection of bowel segments or used alone in bypassing inoperable lesions, is a safe, rational procedure that saves the patient both time and prolonged incapacity. In the treatment of cancer it in no way modifies the radical approach to the eradication of the disease.

Succinate Therapy in Multiple Sclerosis.—Sodium succinate was administered intravenously (20 cc. of a 30% solution) to 10 patients with multiple sclerosis and orally (4 to 5 gm. of powder in 1 oz. [30 cc.] of water three times a day) over prolonged periods to 22 patients with multiple sclerosis. Subjective improvement was reported in 80%, and objective improvement was observed in approximately two-thirds of the patients by both methods of treatment. Follow-up observations on patients treated orally with succinate suggested that approximately one-half have benefited. Beneficial effects consisted of (1) improvement in dyssynergia, ataxia, dysmetria, balance, and gait, (2) improvement in the flexor withdrawal reflex and clonus in some patients, and (3) subjective improvement in the appreciation of vibration and objective improvement in position sense and skin writing. Toxic effects were observed in one patient treated intravenously and in six patients given oral succinate. The toxic reactions to oral administration consisted of gastrointestinal and genitourinary effects and were not alarming. Three of these patients were able to continue treatment with benefit on reduced doses. Deterioration on discontinuance of the succinate was observed in four instances, and all these patients improved when therapy was resumed. Recurrent episodes have been observed in three patients. The rationale for the use of sodium succinate in multiple sclerosis is discussed.

Acid Débridement of Burns.—Attempts have been made to find some agent that would selectively digest or remove the necrotic slough that follows severe burns. Connor and Harvey in 1944 used pyruvic acid starch paste as such an agent, but since this substance had certain disadvantages, other methods were tested. Only phosphoric acid was equal to pyruvic acid in efficiency of slough removal and low degree of irritation. At the Boston City Hospital phosphoric acid (85%) was used as the débriding agent. This was added to a water-soluble vehicle to form a stable 0.7 molar (5%) phosphoric acid gel (pH, 1.02). Immediately after application of the phosphoric acid gel a burning sensation was felt, which lasted from 15 to 30 min. Premedication with small amounts of meperidine (demerol®) hydrochloride or morphine relieved this discomfort. At the first dressing, parallel incisions were made in the slough, to increase the accessibility of the agent to the site of its activity. A dam of petrolatum gauze was placed about the burn to prevent the mixture from seeping away; later, felt strips impregnated with petrolatum were found most satisfactory to accomplish this. The wound was covered with phosphoric acid gel, and petrolatum strips and fluffed gauze were applied over this. Dressings were changed daily or every other day. When the cleavage plane became apparent the separation of partially débrided and undermined areas could be hastened mechanically. Epithelial islands were apparently not damaged by the débriding agent. Areas with first, second, and third degree burns could be treated beneath the same dressing with safety. After débridement, the wounds were dressed with a weak chlorinate solution until the operating schedule permitted skin grafting or, in the case of superficial second degree burns, until healing had occurred. Phosphoric acid gel was employed in 11 cases and proved a simple, safe, selective, and rapid method of débridement. The course of six of these patients is described.

Analgesic Action of Sodium Gentisate.—Forty-three hospitalized medical and surgical patients and 54 ambulatory patients who had pain varying in causation, type, severity, duration, and organ involved received sodium gentisate. The hospitalized patients received 0.3 and 0.6 gm. of sodium gentisate as a single or repeated dose administered orally several times daily. Most of the patients received eight or more doses. The period of observation ranged from one to 55 days. Satisfactory control of pain was achieved in 34 of the 43 hospitalized patients. None of them showed any sign or symptom of toxicity or an untoward reaction to sodium gentisate. The ambulatory patients were advised to take one or two tablets, equivalent to 0.3 and 0.6 gm., respectively, either as a single dose or in repeated doses. The patients were observed for periods of one day to 30 weeks. Of the 54 ambulatory patients, 31 had satisfactory analgesia with the oral administration of either 0.3 or 0.6 gm. of sodium gentisate. Toxicity occurred in six patients (11.1%), of whom four had nausea, one had pruritus, two dizziness, and one abdominal colic. Thirty-five of the 54 patients were observed under similar circumstances for the effectiveness and toxicity of acetylsalicylic acid (aspirin). Nine of these patients noted no difference in relief of the pain from either aspirin or sodium gentisate. Eleven patients preferred aspirin to sodium gentisate, while the remaining 15 preferred sodium gentisate to aspirin. Of the 35 patients who received aspirin, toxic manifestations were noted in 14 (40%). Sodium gentisate, when administered orally, is a safe and effective analgesic for the relief of mild and moderately severe pain. The analgesic potency of sodium gentisate is equivalent to that of aspirin, but it is more useful because of its lower toxicity.

Treatment of Bacterial Pneumonia.—Of 76 patients with bacterial pneumonia, 36 were treated with penicillin and 40 with aureomycin. Most of the penicillin-treated patients received an initial dose of 500,000 units followed by 250,000 units twice a day until they were afebrile for two to three days. The aureomycin-treated patients received an initial dose of 2 gm. of the drug followed by 1 gm. every six hours until defervescence occurred, then 0.5 gm. every six hours until they were afebrile for three days. There were no significant differences in over-all therapeutic response to the two drugs in the two series of patients. In the penicillin series there were two patients, one with a sterile pleural effusion, the other with active tuberculosis, whose temperatures failed to respond promptly. In the aureomycin series there was one death from Staphylococcus pneumonia in a patient with chronic nephritis and uremia. After two days of aureomycin therapy with no improvement, she was given penicillin and streptomycin, which also were ineffective. There were two other patients whose temperature failed to respond promptly; one had a sterile pleural effusion, and the other had Friedländer A bacillus pneumonia, later cured by streptomycin. Fourteen patients (35%) treated with aureomycin had nausea, vomiting, or diarrhea. There was no toxicity from penicillin.

Transmission of Syphilis by Transfusion.—Laboratory studies in experimental syphilis in rabbits have demonstrated that Treponema pallidum becomes avirulent and will not transmit syphilis when present in blood kept under blood bank conditions for 96 hr. or when in plasma processed to the dried state. Under these conditions blood from donors with syphilis should be acceptable for use. The hazard of transfusion syphilis may, therefore, be minimized by the routine processing of blood or blood products. However, the danger of transmission still exists in emergency transfusions with freshly drawn blood from syphilitic donors. In this event, a sterilizing agent, treponemicidal drug, or possibly irradiation would be required. The studies presented in this paper demonstrated that transmission of experimental syphilis in rabbits by transfusion was not prevented by previous exposure of whole blood containing virulent T. pallidum to ultraviolet irradiation, using the Oppenheimer-Levinson quartz chamber apparatus, or to crystalline penicillin G in large quantity, added one hour before transfusion.

Adenomatous Polyps of Colon and Rectum.—The origin, pathogenesis and histopathology of adenomatous polyps of the colon and rectum are reviewed. The relation between the benign adenoma and carcinoma is emphasized in this discussion. A pathological study was made of 800 cases of carcinoma of the large bowel. In 162 adenomatous lesions, there were 26 benign adenomas, 16 adenomas with atypia, 61 adenomata malignum or adenocarcinomas in situ, 24 grade 1 adenocarcinomas, five grade 2 adenocarcinomas definitely arising in an adenoma, and 30 polypoid papillary grade 2 adenocarcinomas. Of this series 90 (11.25%) showed definite histological evidence of having arisen in a benign adenomatous polyp, while 30 (3.75%) presented presumptive evidence of such origin. The criteria for the diagnosis of malignancy are presented, and the importance of the character of the epithelial cells is stressed. Close cooperation between the surgeon and the pathologist is urged for a better understanding of the proper management of this important group of neoplasms. Adequate surgical removal of certain polypoid lesions of the colon and rectum should be carried out, even if this requires radical resection in selected cases.

Adrenal Neuroblastoma: Report of Four Cases. E. Stransky and N. S. Felix.—p. 308.
Impairment of Liver in Toxicosis. O. Tezner.—p. 321.

Insulin Therapy of Chorea Minor.—In investigating the use of insulin in disorders other than diabetes, Mayerhofer studied muscular disorders, because muscle sugar in the form of glycogen is an important source of energy for the skeletal musculature. Two or three daily injections of from 3 to 7 units of insulin, while a lump of sugar was taken by mouth, together with a diet rich in carbohydrates acted favorably on the muscular unrest in the early phase of chorea. This calming effect appears so quickly, that is, after only a few days, that the author believes that it is not so much the result of local formation and storage of muscular glycogen but that it is rather brought about by a central, probably endocrine improvement in neurological regulation, which facilitates better coordination of muscular movements. It is also possible that both factors act synergistically. Although the efficacy of the insulin treatment in chorea minor cannot yet be fully explained, on the basis of experiences in 21 cases, the author recommends the practical application of the new therapy. It is at least as effective as the older therapeutic methods and, in many although not in all cases, it seems to be the best method. The insulin therapy in chorea is also of a certain theoretic interest. The author discusses muscular and particularly endocrine factors that might play a part in the etiology of chorea.

*Significance of Parenterally Administered Amino Acids in Preoperative and Postoperative Management. H. H. Westermann.—p. 153.

Treatment with Intravenous Injections of Amino Acids.—Eleven patients with hypoproteinemia were subjected to a therapeutic trial with parenterally administered 10% elamine (purified casein hydrolysate) solution with dextrose, containing a standardized sterile mixture of amino acids. The patients were divided in three groups, one consisting of patients with preoperative and postoperative hypoproteinemia, the second consisting of surgical patients with undisturbed absorption of food in the presence of an unimpaired intestinal tract, and the third consisting of patients with disturbed absorption of food after surgical intervention on the stomach. The administration of amino acids is of greatest importance in patients with chronic suppurative wounds and in patients with disturbed absorption of food. The elamine solution was as a rule administered by infusion of 50 to 60 drops per minute. For prevention of untoward reactions, such as nausea, vomiting, sensation of heat, and headache, the infusion velocity may be reduced. Treatment with intravenously administered amino acids is contraindicated in patients with cardiac decompensation, severe liver insufficiency, or acidosis. Results in the author's patients showed that a positive nitrogen balance was obtained in most of the patients and the protein serum level was restored to normal in all. There was subjective and objective improvement of the general condition. In the course of 50 intravenous infusions of amino acids, 11 of which were given to a single patient, collapse occurred in only one patient with hydatid cysts in the pleura; it was probably due to an antigen-antibody reaction. Intravenous administration of amino acids should be limited to short preoperative treatment and to treatment during the first postoperative days. To prevent a drop in serum protein values after discontinuation of the intravenous therapy, oral or rectal administration of pulverized or dissolved amino acid mixtures is advisable during convalescence. The amino acid mixtures are more effective than blood transfusions in improving the serum protein level in patients with hypoproteinemia. Treatment with blood transfusions on the day of the surgical intervention to combat shock in patients subjected to extensive surgical interventions combined with subsequent intravenous and oral administration of amino acids appears to be most promising.

Nervous and Mental Disorders in Cushing's Syndrome.—Significant mental and/or neurological disturbances were observed in five of the seven patients with Cushing's syndrome that are reported on in this report. In one patient pituitary irradiation produced apparent clinical cure of the condition, but two years later progressive optic atrophy and cerebral atrophy set in. Four years after treatment the patient was blind, bedridden, and incontinent. Two patients were psychotic in the early stages of the disease. Another patient, who had much emotional instability and was in a neuropsychiatric center for several months, subsequently showed the physical signs of Cushing's syndrome. He also had an attack of unilateral retrobulbar neuritis, which left him with a permanent central scotoma. The fifth patient had considerable depression and alteration of personality in the first year of his illness. In reviewing the literature on the occurrence of nervous and mental disturbances in Cushing's syndrome, Spillane says that many reports do not mention the mental stage of the patient, but he lists 50 reported cases in which there was significant nervous and mental distress. Not included in this list are other cases in which minor symptoms, such as irritability, nervousness, insomnia, forgetfulness, shyness, feelings of self-consciousness and avoidance of social contacts, were the only nervous symptoms mentioned.

Action of Quartz plus Coal or Graphite on Lungs of Rats.—It is generally accepted that silica is the cause of silicosis, but it is not known to what degree nonsiliceous dusts assist or retard the silicotic process, when inhaled with silica. The effect of coal dust has been studied before, especially with reference

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

to its power to increase phagocytosis of siliceous dusts or to absorb the silica released in solution from such dusts. From such studies it had been concluded that inhalation of coal dust should lessen the pathogenicity of siliceous dusts. Many have believed that coal dust protects against silicosis. Others, however, reported cases of acute silicosis from the inhalation of coal dust, and they thought the coal probably hastened the action of the silica. Studies on rats reported in this paper revealed that pure coal dust gives rise to no serious reaction in the animal lungs. Much of it is eliminated, and the amount retained causes only slight reticulinosis. Small doses of quartz that alone produce no lesion in the rats' lungs produce nodular foci of reticulinosis when large amounts of coal dust are added. The large amount of coal probably upsets the drainage mechanism, and the silica retained in the lung exerts its toxic effect with the production of fibrous nodules. Pure graphite was as inert as pure coal, but fibrous nodules were produced when it was mixed with small amounts of silica. It is therefore concluded that the simultaneous presence of large amounts of coal or graphite exaggerated the pathogenic effects of small amounts of silica.

Megaloblastic Anemia and Crystalline Penicillin.—Foy and associates have previously described the favorable therapeutic effects of injections of penicillin G in a nonpregnant woman who had megaloblastic anemia and a histamine-fast achlorhydria. Now they report the use of this substance in a woman with megaloblastic anemia who was six months pregnant. She was given injections of 200,000 units of crystalline penicillin G (sodium salt) twice daily for 17 days. On the seventh day of penicillin treatment her reticulocytes rose to 26%, and there was an improvement in the red blood cell count and hemoglobin. When the injections of penicillin were stopped for about 10 days, the blood cell count remained unchanged or fell slightly. Then the injections were resumed, and, 19 days later, when the patient left the hospital, her erythrocyte count was 4,300,000 and the hemoglobin level 12 gm. The response was rapid, complete, and in every way similar to that obtained with liver, folic acid, and vitamin B_{12}. The marrow reverts to normal, the megaloblasts disappearing rapidly and the giant stab cells more slowly. It is suggested that this response to penicillin may be due to any or all of the following: (1) changes in the intestinal flora, which may lead to the destruction of antagonists or competitors, or other factors which may be interfering with the synthesis, absorption, or utilization of hemopoietic factors; (2) interference with bacterial metabolism, so that hemopoietic factors are released for the use of the body; (3) an effect on protein metabolism and the synthesis of nucleoproteins from basic amino acids; (4) the presence in penicillin of hitherto unknown hemopoietic factors, and (5) the destruction of toxins produced by bacteria.

Roentgen Diagnosis of Gastritis.—Müller asserts that gastroscopy frequently shows a normal gastric mucosa after a previous roentgenologic examination had disclosed changes indicative of gastritis. Comparative gastroscopic tests on 5,100 cases revealed that the roentgenologic diagnosis of gastritis was correct in only 61.7% of the cases. In a group of 1,200 cases the incidence of agreement was only 49%. On the basis of such results, the author denies that the roentgenologic demonstration of the relief configuration of the gastric mucosa is of value in the diagnosis of gastritis.

Kell Erythroblastosis.—Serologic investigations of recent years demonstrated that a significant number of formerly unexplained stillbirths could be traced to serologic incompatibility. The most widely known of these are those in the Rhesus system, but in the Lewis system and even in the classical ABO system of blood groups such serologic incompatibilities are also possible. Other factors have been discovered as the result of transfusion reactions, although they have not as yet been known to produce erythroblastosis. In this paper a case is reported in which the so-called Kell antigen was responsible for pregnancy toxicosis and death of a fetus.

•Brief Considerations on Treatment of 34 Patients with Tuberculous Meningitis in Children's Department of a Hospital, and Results Obtained. P. Bertoye, P. Monnet and J. Thivolet.—p. 457.

Treatment of Tuberculous Meningitis in Children.—Thirty-four children, eight of whom were nursing infants between the ages of 3 and 17 months, with tuberculous meningitis are reported on. Twelve of the 34 patients received streptomycin by the intramuscular route only. Six patients received in addition one course of 15 to 20 intrathecal injections of streptomycin. The remaining sixteen patients received streptomycin intramuscularly and, in addition, intrathecal injections, which were given either daily, to the rapidly deteriorating patients, or in repeated courses of 30 to 45 injections. There were 19 deaths. Recovery resulted in eight patients, seven of whom had been followed up for at least one year after the discontinuation of streptomycin. Six patients are still under treatment, with apparently highly favorable results in four and unsatisfactory results in two. One patient was lost sight of during the fifth month of apparently successful treatment. Only one of the eight nursing infants recovered. Familial contagion was observed in eight children, of whom six died; prognosis is uncertain in the two who survived. For better results with streptomycin therapy in tuberculous meningitis it seems imperative to continue the administration of streptomycin by intramuscular route for more than eight months with either daily injections or intermittent courses and to combine it with intrathecal injections for prolonged periods, until the cerebrospinal fluid has been restored to normal. Repeated courses of 30 to 45 intrathecal injections should be given if necessary. Because of the difficulties of the procedure prolonged hospitalization in a well-equipped hospital is required. Early diagnosis and, consequently, early treatment are of great importance. Diagnosis may be established by the demonstration of Koch's bacillus in the cerebrospinal fluid. Animal inoculation with the cerebrospinal fluid was carried out in 30 of the authors' cases, and positive results were obtained in 26. In the four other cases the diagnosis was established by associated signs and the course of the disease.

Hypertension in Toxemia of Pregnancy.—To determine whether all cases of hypertensive toxemia of pregnancy are of humoral origin and to discover whether the serum concentration of gonadotropins bears any relation to such an origin, the authors studied 140 women in the last trimester of pregnancy, all but 20 of whom had hypertension. Studies of serum gonadotropins, urea clearance, water excretion, and blood urea and the tetra-ethyl ammonium bromide reaction were made in the hypertensive patients. Four patients who had essential hypertension had a low serum concentration of gonadotropins, a normal rate of water excretion and did not react to tetra-ethyl ammonium bromide. The others had hypertensive toxemia and formed two groups on the basis of the above tests. The majority had a high serum concentration of gonadotropins, a diminished rate of water excretion, and no reaction to tetra-ethyl ammonium bromide. A small number had a low serum concentration of gonadotropins, a diminished rate of water excretion, and a reaction to tetra-ethyl ammonium bromide comparable to that seen in normal pregnant patients. It is suggested that in most cases of hypertensive toxemia the hypertension is of humoral origin and is related to hyperfunction of the anterior pituitary.

Chronic Endometritis.—At the turn of the century "chronic endometritis" was a convenient diagnostic label for all cases of excessive or painful uterine bleeding not due to neoplasm and a rationale for their treatment by curettage. It was divided into a glandular type with a thick and hyperplastic mucosa, an interstitial type with stromal inflammatory cells, and various combinations and subdivisions. This concept was discredited when the endometrial cycle was described in 1907. At this time "glandular endometritis" was recognized as a normal stage in the development of the premenstrual endometrium. The diagnosis of interstitial endometritis was retained, however, being restricted to the minority of cases showing plasma cells. The authors review the controversy that arose with regard to the importance of plasma cells in the diagnosis of endometritis. Many writers claim that a persisting primary endometritis is never found, either because a large part of the endometrium is shed each month, or, failing this, because the menstrual flow and vertical position of the uterus provide excellent drainage. Only Schröder seems to believe that infection may persist in the basalis and continue to reinfect the functionalis. Among the conditions with which chronic endometritis is associated, tubal infection is held to be the commonest; others include abortion, uterine polyps, sloughing submucous tumors, recent instrumentation, foreign bodies, cervical stenosis, and, doubtfully, chronic cervicitis. Dumoulin and Hughesdon investigated whether one of these conditions is present when some or many endometrial plasma cells are found, and how reliable the finding of plasma cells is as a guide to the presence of adnexitis, if the uterine causes of endometritis can be excluded. The endometria of 1,240 patients were sectioned, and 66 (5.3%) contained plasma cells. Profuse and/or irregular bleeding was the most frequent symptom; less common were pain, discharge, and infertility. Etiological factors in the form of adnexitis, recent pregnancy, or miscellaneous uterine conditions were found in 42 of the 64 cases, and in 30 of the 34 severest cases, i. e., with more than 10 plasma cells per high-power field. In 22 patients no cause could be found, and some of these apparently had an isolated endometritis. The current view that this does not occur is baseless. Severe endometritis, however, probably does not occur alone; its diagnosis is, therefore, of value, and should be used as an indicator of associated disease. As endometrial pathology has not yet caught up with symptomatology, a known gap in our knowledge, such as isolated endometritis, merits further study.

Action Mechanism of Biologic Reactions of Ultrasonics. O. A. Angerer, G. Barth and W. Güttner.—p. 601.

Intrauterine Radium Irradiation of Corpus Carcinoma.—Czech regards the intrauterine introduction of radium as the most important part of irradiation therapy of carcinoma of the body of the uterus, since women in his clinic who received additional percutaneous roentgen irradiation fared no better than those who had received only intrauterine radium therapy. Because it is difficult to ascertain the exact location of the carcinoma within the uterus, triangular, bucket-shaped, and Y-shaped applicators have been used for better spatial distribution of the radium dosage than is possible with a single rod-shaped holder. The author prefers a packing method in which the uterus is packed with a number of small cylindrical holders of nickel-plated brass, with a top that can be screwed on and off and a loop through which a numbered thread is passed. The continuous numbering makes it possible to follow a certain sequence during the introduction and withdrawal of the holders. A platinum tube, 15 cm. in length with a wall-thickness of 0.3 mm. and holding 10 mg. of radium, is placed into each of the brass holders. A uterus of normal size, having a depth of about 8 cm., is packed with about 12 such holders, larger uteri with up to 20 holders. Measurements on wax phantoms revealed the differences in dosage distribution when one rod-shaped radium holder is introduced and when the uterus is packed with the aforementioned small holders. Dosage problems arising from the close proximity of bladder and intestine to the irradiated uterus are also considered.

Irradiation Therapy in Hypertension.—The results obtained in hypertensive patients with sympathectomy induced Wolf to apply roentgen irradiation to the ganglions of the thoracic sympathetic chain. He applied the rays with a focus-skin distance of 30 cm. to a field 10 by 15 cm. corresponding to the fifth to the 12th thoracic vertebrae, giving a surface dose of 40% of a unit skin dose and a focal dose of 20% of a unit skin dose. The technique used was as follows: 200 kv., 15 ma., 1 mm. Cu, half-value layer 1.5 mm. Cu, and unit skin dose 760 r. Most patients were given first a series of three irradiations at intervals of one or two weeks. Depending on the reaction, additional irradiations were given after six to eight weeks. A total of 34 hypertensive patients were treated, and many of them have been kept under observation for two years. The effects of the irradiation differed in the various forms of hypertension. In seven patients, with so-called pale hypertension, improvement was still not evident after a second series of irradiations. In the other patients a wavelike decrease was noticeable after two to four weeks. On the whole, results were satisfactory. In five patients in whom irradiation of thoracic sympathetic ganglions produced no great improvement, irradiation of the region of the diencephalon was also unsuccessful. The favorable results of irradiation of the sympathetic chain were still evident after 22 months in 12 of 20 patients. Improvement was noticeable particularly in the subjective condition of the patients.

*Pheochromocytoma and Its Diagnosis. Review. J. Riishede.—p. 407.
*Benzodioxan Test in Pheochromocytoma. M. Faber.—p. 413.
Case of Pheochromocytoma in Child. P. Bastrup-Madsen.—p. 420.
Thrombopenic Purpura After Quinidine Sulfate. A. Pinholt Andreasen and R. Christensen.—p. 422.

Diagnosis of Pheochromocytoma. Review.—The increasing number of cases of pheochromocytoma reported during recent years, Riishede says, and the occurrence of two cases in the neurosurgical department of Aarhus Hospital and five cases in nearby hospitals suggest that this usually curable cause of hypertension is not so uncommon as formerly supposed. About 90% of the cases described in the literature developed from the adrenal glands. Endocrine activity seems to be especially pronounced in the tumors localized to the adrenals. The cardinal symptom of the pheochromocytoma is hypertension, which most characteristically is paroxysmal. The disease is thought to pass through the following stages: paroxysmal hypertension alternating with normal blood pressure and increasingly frequent attacks, permanent hypertension with paroxysmal aggravation, and permanent hypertension without characteristic paroxysms. After the intermittent course diagnosis is often impossible. Pharmacologic tests may be helpful in the diagnosis of pheochromocytoma. Of the tests designed to stimulate the discharge of pressor compounds from the tumor and reproduce symptomatic attacks the histamine test is considered the best, but it may be hazardous. The piperoxan (benzodioxan) and dibenamine® (N,N-dibenzyl-beta-chloroethylamine hydrochloride) tests are designed to lower the blood pressure by competitive inhibition of the pressor compounds secreted by the tumor. Abdominal exploration may be necessary. The only method of treatment of pheochromocytoma is operative removal.

Piperoxan Test in Pheochromocytoma.—Faber recommends the piperoxan (benzodioxan) test as a reasonably reliable test for the presence of pheochromocytoma with persisting hypertension. The test is advised first and foremost in all cases of hypertension with symptoms of paroxysmal attacks, also in cases in which the family history gives no information on the occurrence of hypertension. Some form of pharmacologic pheochromocytoma test is advised in every young hypertensive patient without demonstrable renal affection, as a positive outcome in most cases indicates that curative treatment is possible. Pheochromocytoma appears to occur most commonly between the ages of 20 and 50, but cases with symptoms have been reported in patients aged up to 72. Two cases of operatively verified pheochromocytoma are described, in one of which the piperoxan test was negative. Explanations for the negative outcome are suggested.

*Intoxication on Therapeutic Application of Acetylsalicylic Acid in Infants and Small Children with Colds or Pneumonia. T. Iversen and E. Schiødt.—p. 443.
Fibrous Dysplasia of Bones. K. Lundbaek and R. Olsen.—p. 455.

Intoxication on Therapeutic Application of Aspirin in Infants and Young Children.—Iversen and Schiødt discuss the symptoms of acetylsalicylic acid (aspirin) poisoning in young children on the basis of 39 cases from the literature and their four personal cases, in two of which bronchopneumonia was complicated with acetylsalicylic acid intoxication. The main symptom, they find, is hyperpnea. The patient is usually dehydrated, may be apathetic and delirious, and in grave cases coma and shock dominate. There are changes in the acid-base balance, and the electrocardiogram shows prolongation of ventricular systole. In differential diagnosis, pneumonia, myocarditis, sepsis, and diseases causing acidosis are mainly to be considered. Treatment consists of the administration of 0.9% sodium chloride and 5% glucose; 1.3% sodium biocarbonate should always be given, subcutaneously or intramuscularly, but in small doses, during the first stage of the intoxication. The authors assert that acetylsalicylic acid should not be given in the first years of life, cautioning particularly against its application in suspected or proved pneumonia.

Functional Improper Posture with Secondary Myalgia and Improper Posture Resulting from Myalgia. A. Saxl.—p. 301.
Goiter in Young Persons. H. Steiner.—p. 303.
*Experiences with Treatment of Hemolytic Disease of Newborn Infants by Exchange Transfusions or Blood Transfusions. H. Kölbl.—p. 307.

Treatment of Hemolytic Disease of Newborn Infants.—Of 34 newborn infants, 25 boys and nine girls, with severe jaundice, 19 were treated by repeated blood transfusions and 15 by exchange transfusions. Rh incompatibility was present in 32 infants, and A-B-O isoimmunization in two. Transfusions are indicated when the erythrocyte counts reveal a rapid drop below 3,000,000. Rapid deterioration of the clinical picture, the occurrence of cutaneous hemorrhage as a sign of capillary damage, the early occurrence of severe jaundice within the first 12 hr. after delivery and a positive reaction to Coombs' test are decisive criteria for the administration of exchange transfusions. The number of the erythroblasts in the peripheral blood is not decisive. Wiener's cumbersome technique of exchange transfusion was used in only one instance, and the Diamond technique or the modified Gasser technique were preferred by the author. In cases in which the umbilical vein was thrombosed, a polyvinyl catheter was introduced into the saphenous vein and pushed forward to the inferior vena cava, thus facilitating a rapid exchange of blood. About 500 to 700 cc. of blood is required for the largest possible exchange of the blocked erythrocytes of the infant. The author cautions against the use of Rh positive blood for exchange transfusions, since this may produce increased hemolysis, increased bilirubinemia, lower nephron nephrosis, and a rapid and enormous increase of the nonprotein nitrogen values, resulting eventually in death. Thirteen of the 34 infants had kernicterus; four of them were treated by exchange transfusion and nine by repeated blood transfusion. Six of the 13 died. The transfusion therapy has no effect on the kernicterus, which is present at birth. Transfusion treatment is not lifesaving, since danger to life depends on the kernicterus rather than on the anemia. Rh or A-B-O incompatability between mother and infant is not a contraindication to breast feeding.

*Fall of Circulating Eosinophils Following Administration of Epinephrine. H. Braunsteiner, F. Pakesch and H. Vetter.—p. 359.
Antihistamine Preparation Used as Prophylactic in Burns. T. Wense.—p. 362.
Nailing of Pertrochanteric Fractures of Femur. G. H. Marcus.—p. 363.

Fall of Circulating Eosinophils After Administration of Epinephrine.—The fall of circulating eosinophils after the intramuscular injection of 0.3 mg. of epinephrine and the usefulness of this phenomenon as a test for adrenal cortex deficiency was studied in 114 persons. This group included eight patients with a clinical diagnosis of adrenal cortex deficiency, 60 persons who were normal or slightly ill without clinical signs of adrenal cortex deficiency, 20 patients with moderately severe disease, and 26 who were chronically ill. Initial eosinophil counts varied from less than 80 to more than 4,000 cells per cubic millimeter. Results showed that the absence of a 30% or more fall in circulating eosinophils within four hours after the administration of epinephrine on repeated examination presents a highly probable but not infallible indication for adrenal cortex deficiency. The reliability of the test may be impaired by extremely low or high initial eosinophil counts and by chronic diseases. Six of the eight patients with a clinical diagnosis of adrenal cortex deficiency had Addison's disease, for which they had not been treated, and five of these showed a fall in eosinophils of less than 40%. Results of tests of patients with clinically latent or mild adrenal cortex deficiency were not conclusive. Additional experiments showed that *l*-nor-epinephrine has no eosinopenic action, while ephedrine induces a more than 50% fall of eosinophils. The fall of eosinophils after the administration of epinephrine could not be inhibited significantly by sympathicolytic drugs such as N,N-dibenzyl-beta-chloroethylamine (dibenamine®) and dihydroergotamine, or by barbituric acid derivatives, massive doses of desoxycorticosterone or progesterone.

BOOK REVIEWS

Toxicology of Uranium: Survey and Collected Papers. Edited by Albert Tannenbaum, M.D., Director, Department of Cancer Research, Medical Research Institute, Michael Reese Hospital, Chicago. National Nuclear Energy Series, Manhattan Project Technical Section, Division IV—Plutonium Project Record, Volume 23. Cloth. $3. Pp. 333, with illustrations. McGraw-Hill Book Company, Inc., 330 W. 42d St., New York 18; Aldwych House, Aldwych, London, W.C.2, 1951.

A continuation of the long series planned by the United States Atomic Energy Commission, this volume contains reports of animal experiments conducted between 1942 and 1946 on the effects of ingestion and injection of uranium compounds. This work was undertaken because of the need of protecting the many technical workers engaged in the development and production of atomic bombs.

The book is very well written, has a good index, and in general is so designed that it will be exceedingly useful to anyone doing research in the future in this particular field. Material of special interest abounds; an example is the description (pages 274 to 282) of a microfluorometric method capable of determining quantitatively as little as 0.0001 microgram of uranium. The book is naturally not of immediate interest in the practice of medicine but deserves commendation as a most substantial contribution to medical science.

Lehrbuch der Röntgendagnostik. 2.-4. Lieferungen: Skelett. Von H. R. Schinz, W. E. Baensch, E. Friedl und E. Uehlinger. Nebst Beiträgen von E. Brandenberger, et al. Fifth edition. Paper. 70 marks; 82 marks; 84 marks. Pp. 427-878, with 764 illustrations; 879-1406, with 732 illustrations; 1407-1920, with 674 illustrations. Georg Thieme Verlag, Diemershaldenstrasse 47, (14a) Stuttgart O; agents for U. S. A.: Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1950; 1951.

The review of Section 1 appeared in THE JOURNAL Nov. 4, 1950. Sections 2, 3, and 4 are concerned with the skeleton.

Section 2 deals with aseptic necrosis, toxic lesions of bone, inflammatory diseases of bone, certain of the hereditary skeletal defects, and some of the primary neoplasms. One may argue with the validity of listing Paget's disease and Caffey's disease as "inflammatory," but a completely logical classification does not exist, unless one employs a "catch-all" group of diseases of "unknown etiology."

The first 53 pages of Section 3 continue and conclude the consideration of primary malignant neoplasms and are followed by 35 pages on skeletal metastases. The discussion of skeletal anomalies begins with a consideration of the roles played by genetics and by disturbances of physiology of the developing fetus, followed by the generalized anomalies of twins and then of single fetuses. The portion on hypervitaminosis and hypovitaminosis is noteworthy, particularly for the illustrations of severe rickets involving extremities and the sternal ends of the ribs—the so-called rachitic rosary.

The section on disturbances of growth and maturation deals with the various types of dwarfism and gigantism, and under the caption "Hormonal Diseases of Bone" the authors discuss the skeletal results of disturbances of the pituitary, parathyroids, adrenals, ovaries, testes, thyroid, and pancreas. Included, also, are certain forms of osteoporosis, osteosclerosis, and fibrous dysplasia suspected of having a hormonal basis.

The section devoted to joint diseases begins with a protracted discussion of a procedure that has met with little favor in the United States, namely, the direct demonstration of the capsule by injection of positive or negative contrast media—so-called arteriography. Dislocation with and without fracture are well illustrated, and there are included here certain types of fractures that occur in epileptics and in patients subjected to shock therapy.

Arthritis is classified and described in the conventional manner but with the addition of several of the rarely encountered special forms of chronic arthritis. Thirty pages are devoted to hereditary lesions of joints, and here, surprisingly, one finds gout.

Section 4 is devoted to the various diseases of the spine, the skull, muscles, tendons, subcutaneous tissue, blood vessels, breast and the salivary glands, and the localization of foreign bodies. Finally, there are 60 pages of charts, tables, legends, and sketches epitomizing the differential diagnosis of skeletal lesions.

It is only natural that in all three sections the authors have drawn largely on the rich German literature for their text and illustrations, but when they do refer to American work their references usually are to textbooks and secondary publications rather than to basic sources in experimental medicine, surgery, and pathology. Presumably an index will be supplied when all sections of the 5th edition have been published, but the individual sections would have been even more useful than they are at present if each could have had its own separate index, pending the appearance of the cumulative index.

The excellence foreshadowed in Section 1 is continued in sections 2, 3, and 4 and presumably will continue in the numerous sections to follow. These books are a source of complete, authentic, and well illustrated information on specific problems in x-ray diagnosis.

The Enzymes: Chemistry and Mechanism of Action. Volume I, Parts 1 and 2. Edited by James B. Sumner and Karl Myrbäck. Cloth. $13.50; $12.80. Pp. 724; 725-1361, with illustrations. Academic Press, Inc., 125 E. 23rd St., New York 10, 1950; 1951.

Many advances have been made in enzymology in the last several years, and the problems now encountered are of interest to scientists in various fields. Although enzymes originally may have been of interest principally to the biochemist, they have become the subject of study in all the biological sciences as well as the fields of organic and physical chemistry.

In order to evaluate properly the progress made and at the same time point out the many problems still to be investigated, it was desirable to bring together in a comprehensive survey the work that has been done in the enzyme field. This was the thought in mind in the planning of this two-volume series on enzymes, which will be published in four parts. The various aspects of enzymology will be covered by some 87 authorities from Australia, Europe, and the United States.

Part 1 of Volume I contains an introductory chapter by the co-editors of this series. It contains several generalities concerning enzymes, such as their chemical nature, general properties, and the determination of their activity, as well as the definitions, terminology, and classification commonly used in enzyme chemistry. Chapters 2 through 8 deal with certain chemical or physical aspects of enzymes which may be considered to be held more or less in common by all of them. Kinetics, specificity, adaptation, inhibition, and also the role enzymes play in immunochemistry and chemotherapy and their relation to cell chemistry, viruses, hormones, and vitamins are discussed. Chapters 9 through 19 include specific enzymes or groups of enzymes. Among these are the fat and ester hydrolyzing enzymes, cholinesterase and acetylcholinesterase, phosphatases, sulfatases, alpha-D-glucosidases, and beta-glucosidases and other sugar-splitting enzymes, amylases, beta-glucuronidase and invertase.

Part 2 of Volume I is a continuation of the study of the various specific enzymes or enzyme groups. It contains 24 chapters dealing with enzyme groups, such as the cellulases, desulfhydrases, mucopolysaccharases, phosphorylases, transaminases, and transmethylases, and the specific enzymes: carbonic anhydrase, aspartase, fumarase, aconitase, enolase, thiaminase, penicillinase, histidase, urocanase, hippuricase, allantoinase, allantoicase, arginase, and urease. Other class enzymes discussed are the pectic, proteolytic, and nucleolytic enzymes. The role of enzymes in blood and milk coagulation as well as their presence in bacterial and animal toxins are also included.

Since each chapter is prepared by a different authority, the organization of the chapters and the material discussed at length differ considerably. Overlapping and repetition, which might be expected in a book prepared by 87 authors, appear to be minimal.

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

Each chapter has appropriate references, including material as recent as 1950. It has been impossible to include in detail everything that is available; however, some procedures are included where they appear necessary. Part 2 contains the author and subject indexes for both parts of the volume. The series can almost be considered a must for workers or prospective workers in enzymology, whether they are in the medical field, in organic or physical chemistry, biochemistry, zoology, bacteriology, or in any of the other divisions of the biological sciences.

Climate in Everyday Life. By C. E. P. Brooks, I.S.O., D.Sc., F.R.Met. Soc. Cloth. $4.75. Pp. 314, with 34 illustrations. Philosophical Library, Inc, 15 E. 40th St., New York 16, 1951.

From the rich and numerous but widely scattered sources of information on climatology, Brooks first assembled facts for a lecture on climate and the deterioration of materials; this grew into a book on industrial climatology, and finally became the present even more inclusive volume. Its three major divisions are headed "Living with the Climate," "Climate as an Enemy," and "The Control of Climate." The third is of particular medical interest because it includes discussions of heating, air conditioning, lighting, and clothing. Readers curious about the new word "clo" will find a definition on page 254. The surprising integrations of modern life are exemplified on page 252, where the author notes the increased drain on the electric generator systems when a dense thundercloud darkens the sky over a great city. The author's discussion of lighting is far from complete, and in general it becomes evident that the subject of climatology, even in its purely medical aspects, has grown to the point where it can no longer be covered in detail in a volume of this size. Nevertheless, the author deserves credit for having produced a work that is replete with both information and inspiration.

Essentials of Nutrition. By Henry C. Sherman and Caroline Sherman Lanford. Third edition. Cloth. $4.25. Pp. 454, with 36 illustrations. The Macmillan Company, 60 5th Ave., New York 11, 1951.

The newest edition of this popular textbook has been brought up to date and revised in the light of our rapidly expanding knowledge of the science of nutrition. All the data on the nutrient content of foods have been revised to conform to the governmental publication of June, 1950. The authors have not merely added new sections to the different chapters but have completely rewritten them, incorporating the results of recent nutritional research. The bibliography at the end of each chapter has been expanded to include references to basic nutritional research performed since the previous 1943 edition. There is a short discussion of the newer specific factors for calculating the caloric values of foods, and a table in the appendix gives a comparison of these values with those arrived at by the commonly used Atwater factors. Examples of the long-term benefits to be derived from the liberal intake of calcium and vitamin C are also cited. As the authors say in the preface, ". . . today's essentials of nutrition deal with potentialities beyond those that the science of yesterday thought possible."

This book can be highly recommended for use in the teaching of nutrition courses in colleges and nursing schools, and any person who desires a brief comprehensive survey of the field of nutrition will find it of particular value.

Medicinal Chemistry. Volume (E.S.) I. C. M. Suter, Editor-in-Chief. Series of reviews prepared under auspices of Division of Medicinal Chemistry of American Chemical Society. Cloth. $12. Pp. 473. John Wiley & Sons, Inc., 440 4th Ave., New York 16; Chapman & Hall, Ltd., 37-39 Essex St., Strand, London, W.C.2, 1951.

This is the first of a series of volumes sponsored by the Division of Medicinal Chemistry of the American Chemical Society. The stated purpose of the series is "to summarize the available data on the biological properties of medicinal substances and to correlate the relationship between chemical structure and physiological activity in each area covered."

The areas covered in this volume are antithyroid compounds, antispasmodics, antibiotics from plants, benzoates and substituted benzoates as local anesthetics, and analgesics divided into the aralkylamines and partial structures related to morphine. The same general plan is followed for each topic: lists of all compounds that have been tested for a given pharmacological activity, relationship between chemical structure and pharmacological action, brief discussion of methods of synthesis and pharmacological test methods, and inclusion of an extensive bibliography, including references to patents.

There are a great number of tables comparing the activities of numerous compounds organized according to chemical structure. The authors are industrial research workers active in the fields about which they write. The work meets a great need among chemists and pharmacologists who synthesize and evaluate drugs.

Pain and Its Problems. Edited by Sir Heneage Ogilvie, K.B.E., D.M., M.CH., and William A. R. Thomson, M.D. Practitioner Handbooks. Cloth. $3. Pp. 194. The Blakiston Company (Division of Doubleday & Company, Inc.), 1012 Walnut St., Philadelphia 5, 1950.

This is a compilation by various authors of their original short review articles which appeared in *The Practitioner*, plus certain additional chapters. It is by far the best available small monograph on clinical pain. Certain subjects, such as headache, are sketchily disposed of, but the treatment of other types of clinical pain is more than adequate. The two chapters on the drug treatment of pain can be criticized for the use of such typical British drug names as pethidine (meperidine) and omnopon. A few explanatory footnotes might have made the American edition more useful for those practitioners who are unfamiliar with British drug names.

Patterns of Sexual Behavior. By Clellan S. Ford, Ph.D., Associate Professor of Anthropology, Yale University, New Haven, and Frank A. Beach, Ph.D., Professor of Psychology, Yale University, New Haven. With foreword by Robert Latou Dickinson, M.D. Cloth. $4.50. Pp. 307, with 16 illustrations. Paul B. Hoeber, Inc. (Medical Book Department of Harper & Brothers), 49 E. 33d St., New York 16, 1951.

Development of serious interest in the problem of sex education and how it may be carried out most successfully make this volume especially desirable, because all too often those attempting to provide such education have little or no knowledge regarding the evolution of sex behavior in man. The authors have made a survey that includes American society, 190 other peoples, and several groups of animals in the same subclass of mammals. The recognition that there is an extremely wide variation in attitudes regarding sexual behavior could conceivably have a salutary effect on the way in which some sex educators approach their task. The nature of coitus, sexual attractiveness and stimulation, homosexual behavior, and physiological factors in sex behavior are developed in 12 chapters, with a final summary chapter. A glossary and an extensive bibliography are also included.

Advances in Enzymology and Related Subjects of Biochemistry. Volume XI. Edited by F. F. Nord. Cloth. $9. Pp. 471, with illustrations. Interscience Publishers, Inc., 250 5th Ave., New York 1; Interscience Publishers, Ltd., 2a Southampton Row, London, W.C.1, 1951.

As in the other volumes in this series, there are reviews by experts of recent advances in various fields of biochemistry related to enzymes. Thus there are chapters on the biochemical role of entropy by Gutfreund, on reactions at interfaces (including information on toxicity of ions, oxidation of sterols, and action of snake venoms on surface films) by Danielli and Davies, on chlorophyll by Wassink, on pectic enzymes by Lineweaver and Jansen, on transformations of starch by Peat, on alliin (including a short discussion on possible use in therapy) by Stoll and Seebeck, and on wilting in plants by Gäumann. Of most interest to medical scientists, though, are the chapters on the thiol groups of biological importance by Barron of the Chemical Division, Department of Medicine, University of Chicago, and on enzymic synthesis of polysaccharides by Hehre of the department of bacteriology and immunology, Cornell University Medical College. The indexes to this volume are supplemented by a cumulative author index to the series. The printing and binding are excellent.

QUERIES AND MINOR NOTES

EFFECTS OF SECONDARY X-RADIATION

To the Editor:—*I perform on the average of four retrograde pyelograms a week. I use a standard urological table, stand at the foot of the table to inject the contrast media, and remain there during a second and sometimes a third exposure. The tube is a CRT 1-2 Coolidge X-ray Tube Unit. My questions concern the effects of secondary x-radiation that one would be exposed to in the use of this particular tube. Is there a possibility of radiation sterility or other detrimental x-radiation effects? There is no cone or filter on our tube, and we use the small focal spot.*

M.D., Florida.

Answer.—The dosage rate of primary and scattered radiation received by the operator depends on the kilovoltage, milliamperage, and time factors employed, as well as the individual output characteristics of his particular x-ray tube in its housing and the location in which it is used. It also depends on the distance the operator maintains from the x-ray tube, the patient, and the cassette during the exposure. The dosage rate the operator receives should therefore be checked by an instrument that measures ionizing radiations. Such a service can undoubtedly be obtained from the manufacturer of the equipment the operator uses; it is suggested that he communicate with the company's representative or arrange for some qualified person in his locality to measure the radiation in question. The possibility of detrimental effects can only be evaluated after the dosage and an estimate of the quality of the radiation are known. The problems should not be neglected.

It is also suggested that a suitable cone and filter be employed for the protection of both the patient and the operator against unnecessary exposure to ionizing radiations and so that better roentgenographic definition may be obtained.

INFECTIOUS HEPATITIS AND "SPLIT EYE"

To the Editor:—*Is there any relation between infectious hepatitis in humans and "split eye" in poultry, characterized by enlarged liver and transmitted by the droppings from one chicken to another? Infectious hepatitis recently developed in two elderly patients; they eat three to four dozen eggs a week from their own flock. A case of "split eye" was detected in their flock two months before the first case. The second case developed almost exactly 60 days after the first one.*

Arnold C. Tait, M.D., Sunnyside, Wash.

Answer.—Infectious hepatitis of human beings appears unrelated to the various expressions of the avian leukosis complex (ALC), of which ocular lymphomatosis, also occasionally called "split eye," is considered a part. While both diseases are attributed to virus agents, the properties of each agent and disease are distinctive and divergent. Ocular lymphomatosis is characterized by mononuclear cell infiltration, which is apparent chiefly in the iris. This expression of the ALC may be accompanied by hepatolymphomatosis, which, in turn, may be manifested by slight to massive lymphomatosis of the involved organ and is similarly due to an oncogenic agent. Concentric annular or spotty depigmentation or diffuse bluish gray fading of the iris, in one or both eyes, commonly results. The pupil may become irregular with angular indentations ("split eye") and gradual loss of light accommodation. The iris, in advanced cases, is diffusely gray with pinpoint pupil. Slightly turbid exudate collecting in the anterior chamber tends to increase the convexity of the cornea as in glaucoma.

Havens and Paul (in Rivers, Viral and Rickettsial Infections of Man, Philadelphia, J. B. Lippincott Company, 1948) emphasize the characteristic diffuse involvement of the liver in infectious hepatitis in man. There is early and diffuse parenchymal destruction of this organ in contrast to the chronic, largely noninflammatory cellular infiltration that typifies the classic ocular lymphomatosis of domestic fowl and other birds.

HORMONAL BALANCE OF PREGNANCY AND THE MENOPAUSE

To the Editor:—*In women, either during pregnancy or the menopause, occasionally bright red capillary nevi, 1 or 2 mm. in size, develop on the chest, breast, and upper abdomen, sometimes accompanied by moist red palms and painful, fissured pale tongue. What hormonal imbalance, if any, do these women have in common? Is there any connection between protein and liver metabolism, vitamin B deficiency, low estrogen, and high circulating levels of follicle-stimulating hormone? These are not the usual "spider nevi," and none of these women have cirrhosis or alcoholism.*

M.D., Massachusetts.

Answer.—The hormonal balance of pregnancy differs greatly from that of the menopause; in the latter there is a deficiency of estrogen. During pregnancy large amounts of estrogens circulate in the blood and are present in the tissues of the body; in addition, there are unusually large amounts of progesterone as indicated by pregnandiol excretion as well as the high titers of chorionic gonadotropin, which are the basis for many of the pregnancy tests depending on ovarian stimulation in animals. It is therefore highly doubtful that the capillary changes and the fissured tongue have a common endocrine etiology. However, in a deficiency of estrogen, such as occurs in the menopause, capillaries are more fragile. Fissuring of the tongue has little or no relation to estrogen deficiency, although it is known that the mucosa of the mouth and nose may undergo a degree of atrophy in the presence of estrogen deficiency. Whether this may be reflected in changes in the tongue epithelium is not well established. There is little physiological basis for an explanation of such changes during pregnancy. There are typical epithelial changes during pregnancy, such as hypertrophy of the gums, herpes, and petechia, but it is difficult to correlate these changes and those mentioned in the question.

There is a definite relation between liver metabolism and the estrogens. When the liver functions poorly because of organic lesions, protein deficiency, or a vitamin B deficiency estrogens are not destroyed normally, with a resultant increase in circulating estrogenic hormones. This should result in a low level of follicle-stimulating secretion by the anterior pituitary. In long-standing liver diseases, capillary disturbances may appear, and these are possibly due to excessive estrogen over a long period of time. It is doubtful that this situation occurs during pregnancy because of the elevated titers of estrogen.

ASTIGMATIC MICROSCOPISTS

To the Editor:—*For a person unable to wear glasses when working with the microscope, do you know of any arrangement for getting around this difficulty, such as having lenses made from the oculist's prescription fitted over the eye pieces?*

M.D., Michigan.

Answer.—Ordinarily a person working with a single eye piece microscope can compensate enough for the absence of glasses by adjusting the microscope. When substantial astigmatism is present, or if there is a sharp difference in visual acuity based on refractive errors, and a binocular microscope is used, correction usually can be made by adjusting each focussing eye piece separately. To provide for astigmatism of a high degree, it is possible to have the astigmatic portion only of the person's glasses ground into a small lens, which is mounted in a rubber gasket and slipped over the eye piece and set in a definite axis. The latter correction may be monocular or binocular.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

ASCARIASIS

To the Editor:—*I have several young patients who began passing adult ascarides after oral penicillin therapy for various illnesses. There are no symptoms referable to the infestation, but three of the children still show fertilized ova in repeated stool examinations. I would appreciate suggestions.*

Harold A. Wente, M.D., Rochester, Minn.

Answer.—Hexylresorcinol in hard gelatine capsules (crystoids® anthelmintic) is the drug of choice. This drug is less toxic and more efficient than the others. The capsules must be swallowed without chewing, for the chemical is irritating to the buccal mucosa. Even young children can be taught to swallow pills by practicing first with placebos. The drug is taken in the morning on an empty stomach. No preliminary purge is needed. Food is withheld for five hours. Two hours after administration of the drug a saline purge is given to rid the patient of dead and dying worms. The dose recommended for adults is 1 Gm.; the dose for preschool children is 0.6 Gm., and for children from 6 to 10 years of age the dose is 0.8 Gm.

Hexylresorcinol yields about a 90% cure. It does not kill the larvae outside the intestinal tract, so that treatment may have to be repeated in one week. Reinfection, of course, should be avoided. The tablets must not be too old, for in such cases the hexylresorcinol tablets may not dissolve high enough in the bowel to be effective.

Milk of higueron from Central America is an efficient drug in elimination of ascarides. Its action is that of a proteolytic enzyme which is extracted from the fresh sap of Ficus glabrata and doliario.

BALATA AS AN ALLERGEN

To the Editor:—*Have you had any reports of epidermal or respiratory symptoms in persons who have been working with webbing impregnated with balata?*

Clifford H. Kalb, M.D., Milwaukee, Wis.

Answer.—On a precise basis balata is the sap or dried gum of Mimusops globosa, a tropical or subtropical tree. Less precisely, the term is applied to a variety of vegetable gums, including at times chicle or zapota. Millions of golf balls have had casings of balata without known harm to golfers. In this and similar manufacturing operations, the balata requires solution such as in benzene, carbon disulfide and kerosene. Clearly, exposures to these several solvents could lead to dermatitis or systemic damage. Balata is credited, by Schwartz and Tulipan, with a capacity to provoke dermatitis. The balata of golf balls and presumably that appearing on impregnated textiles is well polymerized and freed of solvent after full drying, but balata as introduced into machinery belting dressings may exist in a more liquid state. The nature of the "webbing" mentioned in the query is not stated. If this represents jute, it may be recognized that this vegetable matter may induce both dermatitis and bronchitis from its dust. It is suspected that balata, if incompletely polymerized, may constitute an allergen just as the highly useful gum acacia is a known allergen. Judiciously applied patch tests might establish sensitivity to balata or to the unimpregnated fabric.

BLOOD AND SPINAL FLUID SEROLOGIC TESTS

To the Editor:—*When the blood Wassermann test for syphilis is positive, is the spinal Wassermann test always positive and vice versa, in the same case? In case they do not always agree, in what ratio are they always the same?*

W. C. Hensyl, M.D., Berwick, Pa.

Answer.—Patients with positive serologic reactions for syphilis do not necessarily have positive spinal fluid Wassermann reactions, unless there is a syphilitic involvement of the central nervous system. Furthermore, most patients with syphilis of the central nervous system will present positive serologic reactions in the serum. Only on rare occasions will a patient have neurosyphilis with positive serologic reactions of the spinal fluid and negative serologic reactions of the blood.

SIMMONDS' DISEASE

To the Editor:—*A 24 year old, single woman office employee has nausea, vomiting, weakness, loss of appetite, insomnia, pain in the right lower abdominal quadrant and gradual loss of weight from 120 to 82 pounds (54 to 37 Kg.) in the past year. Her hair is graying, and her scalp and skin are dry. Past history includes appendectomy in 1946, exploratory operation for cystic ovary again in 1946 (ovaries are intact) and exploratory operation for adhesions in 1948. She has had no serious illnesses. Menarche occurred at age of 13. The menses were regular, every 28 days, until the appendectomy in 1946, after which periods occurred every three to six or seven weeks. Last menstrual period was December 1949. Her height is 62 inches (157 cm.) blood pressure 82/56 and basal metabolic rate — 28 per cent. Barium examination of the colon disclosed no abnormalities. The kidneys are normal in size, shape and position. Roentgen examination of the skull revealed a normal sella turcica, no evidence of erosion or bone distruction about the sella; bones of the vault are normal, and there is no evidence of chronic pressure. Results of pelvic and rectal examinations were completely negative. Red blood cells numbered 3,800,000, and hemoglobin was 76 per cent. Is this sufficient for a diagnosis of Simmonds' disease? Please outline treatment.*

Stephen R. Minor, M.D., Worcester, Mass.

Answer.—The data presented are not sufficient to permit a diagnosis of Simmonds' disease. One would expect atrophy of the breasts, absent pubic and axillary hair and atrophy of the vaginal mucosa. In addition to the basal metabolic study, laboratory studies measuring the function of at least two other glands are necessary: (1) function of the pituitary to be determined by the excretion of the follicle-stimulating hormone in the urine, the insulin tolerance test and the response of the eosinophils to epinephrine and (2) function of the adrenal cortex to be determined by the excretion of the 17-ketosteroids and of the 11-oxycorticosteroids in the urine, the level of sodium, potassium and chloride in the blood and the Cutler-Power-Wilder test. Studies of the ovarian function may also yield valuable information, namely, vaginal smear, endometrial biopsy and excretion of pregnandiol in the urine.

The treatment of Simmonds' disease resolves itself into the treatment of thyroid hypofunction, plus the associated hypogonadism and hypoadrenocorticism. Thyroid by mouth, starting with 30 mg. and increasing slowly to 60 mg. should be administered. Extra salt by mouth, as well as 4 to 6 Gm. of salt in tablet form, should be kept up indefinitely. Small doses of testosterone 10 to 25 mg., given intramuscularly twice a week, help protect against adrenocortical failure in either sex. In females moderate doses of estrogens may replace testosterone. In young patients chorionic gonadotropin, in doses of 500 to 1,000 units intramuscularly twice a week will stimulate the gonads satisfactorily. Cortisone or pituitary adrenocorticotropic hormone (ACTH) may be used to improve the adrencortical insufficiency in this disease. Small doses (25 to 50 mg. daily) may be given over a prolonged period of time.

PTYALISM DURING PREGNANCY

To the Editor:—*What is the treatment of ptyalism associated with pregnancy? A 32 year old woman, gravida II, experienced ptyalism during her first pregnancy. She is now in her second month and, due to excessive salivation, is having discomfort. Tincture of belladonna and pyribenzamine® have been employed with no marked relief. For a short time the latter appeared to be of some aid, but, because of the side effects and the pregnancy, it was discontinued. Are there any nontoxic drugs that are effective in controlling the ptyalism?*

Herman Rice, M.D., El Paso, Texas.

Answer.—Ptyalism, a rare complication of pregnancy, is related to hyperemesis and may occur alone but is generally associated with nausea and vomiting. It usually begins in the second month, ceases about the fifth month or at quickening, presents the same variations as vomiting and almost always ceases with parturition, but it has been known to continue for a few weeks thereafter. It usually occurs only once but may appear in successive pregnancies and may be absent in one and recur in another. The flow varies in amount; excessive quantities have been reported—more than 1,920 cc. (2 quarts) a day. It usually lessens during the night but may continue unabated. The saliva is watery, tasteless, odorless, limpid and not acid; it has little ptyalin. The patient cannot swallow the saliva, and it nauseates her.

Ptyalism occurs more often in psychotic women. The diagnosis is not difficult, since mercurial salivation is attended by fetor and stomatitis. The treatment is similar to that of hyperemesis. The drain of this large amount of fluid, the absence of digestive powers and the loss of appetite can produce a condition of exhaustion, which resembles that produced by intractable vomiting and on rare occasions has been an indication for termination of pregnancy.

CYSTITIS FOLLOWING INTERCOURSE

To the Editor:—*A 41 year old white woman has had cystitis following intercourse many times during her married life of 10 years. Her general health previously and now has been excellent. The cystitis always follows intercourse by one to three days and never occurs other than at that time. Such attacks are easily terminated by the use of such agents as sulfonamides, aureomycin and mandelamine. Between attacks there are no abnormal urinary findings or symptoms. In 1941, a few months after marriage and following the second attack of cystitis, cystoscopic findings and retrograde pyelograms were normal. This patient has had two normal pregnancies with no complications. The genital tract is still normal. No urinary cultures have been made; however, a Gram stain of the urine sediment always shows a gram-negative, motile bacillus. The urine is always acid. What is the probable cause of so many recurrences, and what can be done to prevent them?*

James T. Hardy, M.D., Lake Worth, Fla.

Answer.—The first step in the solution of this patient's problem is a very careful examination of her genital tract. The inquiry states that results of the gynecological examination were negative, but it does not state how recent this was. The second step is cystoscopic examination, x-rays and intravenous pyelograms. The inquiry states that when these were made some years ago they were normal. The third point is the condition of her intestinal tract. Many patients with recurring attacks of so-called cystitis suffer from diseases of the gastrointestinal tract, such as cathartic colitis, spastic colitis, constipation, hemorrhoids and amebiasis. Therefore, this possibility must be ruled out. Last, but not least, is the significant statement that these attacks of cystitis follow intercourse. This is significant in view of other statements that everything else has been normal. If results of the genitourinary examination, the gynecological examination and the examination of the intestinal tract are all negative, there probably is a psychic element in this case, and she should consult a psychiatrist. It would be interesting to know whether sexual intercourse was painful. This clinical picture is not so uncommon.

LOW SPERM COUNT

To the Editor:—*What effects, if any, have cathode rays or any other rays present in certain departments of television companies? A healthy married man in his twenties, who is the father of a 4 year old child, born when he was a milk driver, now has a sperm count of only 6,000,000, with 50 per cent motile (high power field) and 8 to 10 pus cells. There is no history of gonorrhea. If these rays have no effect on spermatogenesis, what, if anything can be done to stimulate sperms? The wife is normal but has not become pregnant again. Workmen at this television company are of the opinion they are being exposed to a certain amount of x-rays given off by the television sets.*

A. E. A. Wanderer, M.D., Oak Park, Ill.

Answer.—It is hardly likely that the amount of cathode rays associated with television machines can penetrate deeply enough into the body to produce sterility. Therefore, some other cause for the low sperm count should be looked for. Generally, the attempts to increase a man's sperm count are not very successful. Nevertheless, every effort should be made to try to increase the procreative ability of the man. The diet should be discussed with the patient, because occasionally an improper diet may be responsible for impaired fertility. Vitamins, such as A and E, have been prescribed, but an impartial analysis reveals that these have not helped much to stimulate spermatogenesis. Other vitamins have not been tried out sufficiently.

In the discussion with this patient, the matters of excessive amount of work, fatigue, marital troubles and other anxieties should be discussed. Every effort should be made to overcome tiredness, overwork, excessive use of alcohol and sedentary habits. If the patient is overweight, an effort should be made to reduce the excess.

Endocrine products are being used extensively to increase spermatogenesis. The following substances are in use: (1) thyroid extract, (2) chorionic gonadotropins, (3) pituitary gonadotropins, (4) mare's serum gonadotropins and (5) androgens. In patients with hypothyroidism, thyroid extract is of distinct benefit; otherwise it usually is not of much help. The results with the gonadotropins are far from good, and some men will have foreign protein reactions from these gonadotropins. The male sex hormones are used, but they may be without benefit and may actually depress spermatogenesis.

It must be realized, therefore, that at present there is no satisfactory hormone treatment for defective spermatogenesis, but improvement can be obtained in some cases. There is as yet no specific sexual hormone with which to increase spermatogenesis.

SUBSTANCES USED TO STIMULATE FIBROUS TISSUE

To the Editor:—*The answer to the query on this subject in* The Journal *June 2, 1951 (page 509) makes no mention of work by Boyd, Saint, and me on the treatment of thoracic and abdominal aneurysms of syphilitic and arteriosclerotic origin by the periarterial injection of dicetyl phosphate dissolved in olive oil* (J. Indiana M. A. 42:889 [Sept.] 1949). *I discussed this subject before the Central Surgical Association in February, 1951, at which time I reported that 0.9% dicetyl phosphate dissolved in olive oil produced an enormous amount of fibroplasia when injected around blood vessels in experimental animals. The olive oil must be heated to body temperature in order to keep the dicetyl phosphate in solution.*

We recently received a supply of sodium dicetyl phosphate from the Monsanto Chemical Company. This is a tribasic salt with two hydrophilic radicles, namely, sodium and phosphate. This leaves the dicetyl component as a suspension which is easily injectable and does not require heating. Moreover, the strength of the solution may be greatly increased over that used in olive oil. Dicetyl phosphate has been used in the treatment of aneurysm in four patients. The results have been very promising. As soon as a sufficient time for proper evaluation has elapsed, a report will be made of the clinical results.

J. K. Berman, M.D.,
23 E. Ohio St., Indianapolis 4.

DIAPER RASH

To the Editor:—*In Queries and Minor Notes in* The Journal *(146:416 [May 26] 1951), a question is raised concerning ammonia dermatitis and its treatment with regard to possible agents given internally. This question was not directly answered, and no mention was made of oral preparations that could be used as prophylaxis or treatment. I would like to call attention to the article "Napkin Dermatitis Caused by Ammoniacal Urine: Treatment with Methionine" (Goldstein:* Arch. Pediat. *66:553-560 [Dec.] 1949). This is a practical paper, and a theoretical discussion of mode of action is presented.*

THE PSYCHOLOGICAL MANAGEMENT OF CANCER CASES

Nathan S. Kline, M.D., Worcester, Mass.
and
Julius Sobin, M.D., Newark, N. J.

Improved methods of cancer detection and public education on the subject mean that physicians are seeing and treating many more malignant lesions than ever before. More widespread lay knowledge about cancer has almost resulted in a situation in which "every man is his own diagnostician." Formerly, cancer was almost unmentionable between patient and physician, and most persons did not wish to know nor expect to be told of such diagnoses. The pendulum has swung far in the opposite direction, and, along with its benefits, the educational campaign has resulted in an almost national cancerphobia. Our civilization breeds guilt feelings of one form or another in almost all of us; since guilt tends to seek out a "punishment" the cancer-education campaign has provided potential punishment for many persons.

In any case, the attitudes of cancer patients have altered significantly in the past 10 years, and not the least of the problems is the psychological management of these cases. In medical school lectures, it is generally customary in an outline of the treatment for virtually any chronic illness to list psychotherapy as the final item under treatment. Usually the elaboration of this point consists only of a suggestion to "help the patient adjust to his condition." The how's, why's and wherefore's are seldom discussed. Although each physician handles not only his cases in general differently but each patient somewhat differently from any other, it is felt that a general review of the problem may be helpful and suggestive.

TO TELL OR NOT TO TELL?

Unlike tuberculosis, where danger of contagion makes informing the patient of the nature of his illness practically mandatory, in cancer there is a distinct and sometimes painful choice to be made. Certain considerations are involved in making this decision.

1. The physician should be absolutely certain of the diagnosis. Until he is certain, any action that might arouse suspicion by the patient of the nature of his illness should be avoided. It is best even to dissimulate at this stage. There must be some appreciation, however, of the severity of the patient's symptoms. Unless it is impressed on the patient that the condition may be serious, difficulty may arise in having him follow through with the necessary diagnostic procedures. If he questions the necessity for these additional tests, a suggested approach would be "I want to make certain this is only lymphadenopathy" (or hemorrhoids or another condition). If subsequently the diagnostic procedures give normal results, the patient has been spared from severe psychic trauma, and, if the evidence shows abnormal conditions, few patients will not understand that the physician was attempting to spare them anxiety until he himself was certain.

Mention of disease should always be coupled with stress on the need for treatment: "The symptoms will become annoying or dangerous unless you follow through with treatment." When some patients learn that their illness is likely to be fatal they feel that treatment is useless. It must be emphatically pointed out to these patients that no illness is absolutely fatal, and that, with proper treatment, there is at least some chance that they will recover. That they owe the obligation to undergo treatment not only to themselves but to their families is worth stressing, if this reaction occurs.

2. Unless there are strong indications to the contrary, it is advisable to wait until the patient asks. With the widespread knowledge of cancer symptoms, it is inevitable that those patients who want to know will eventually present the physician with this opportunity.

3. The major consideration of the physician in deciding whether to conceal from the patient the nature of his illness should be the way he manages other life situations. It will probably be better for those persons who have a realistic approach to life in general to know the truth. To judge the realism of their general attitude does not require profound psychiatric training. The patient who in the past has inquired how much an operation will cost, how long he will be incapacitated, and the other "hard facts" is usually the realist.

4. If the patient does ask, the way he phrases his question may give a strong indication as to the type of answer he desires. The "I don't have cancer, do I?" phraseology is really only a request for negative reassurance and in all likelihood should be met with the tactics of evasion. Physicians have all had experience with the mother who asks about the possibility or the unlikeli-

thereafter. It usually occurs only once but may appear in successive pregnancies and may be absent in one and recur in another. The flow varies in amount; excessive quantities have been reported—more than 1,920 cc. (2 quarts) a day. It usually lessens during the night but may continue unabated. The saliva is watery, tasteless, odorless, limpid and not acid; it has little ptyalin. The patient cannot swallow the saliva, and it nauseates her.

Ptyalism occurs more often in psychotic women. The diagnosis is not difficult, since mercurial salivation is attended by fetor and stomatitis. The treatment is similar to that of hyperemesis. The drain of this large amount of fluid, the absence of digestive powers and the loss of appetite can produce a condition of exhaustion, which resembles that produced by intractable vomiting and on rare occasions has been an indication for termination of pregnancy.

CYSTITIS FOLLOWING INTERCOURSE

To the Editor:—*A 41 year old white woman has had cystitis following intercourse many times during her married life of 10 years. Her general health previously and now has been excellent. The cystitis always follows intercourse by one to three days and never occurs other than at that time. Such attacks are easily terminated by the use of such agents as sulfonamides, aureomycin and mandelamine. Between attacks there are no abnormal urinary findings or symptoms. In 1941, a few months after marriage and following the second attack of cystitis, cystoscopic findings and retrograde pyelograms were normal. This patient has had two normal pregnancies with no complications. The genital tract is still normal. No urinary cultures have been made; however, a Gram stain of the urine sediment always shows a gram-negative, motile bacillus. The urine is always acid. What is the probable cause of so many recurrences, and what can be done to prevent them?*

James T. Hardy, M.D., Lake Worth, Fla.

Answer.—The first step in the solution of this patient's problem is a very careful examination of her genital tract. The inquiry states that results of the gynecological examination were negative, but it does not state how recent this was. The second step is cystoscopic examination, x-rays and intravenous pyelograms. The inquiry states that when these were made some years ago they were normal. The third point is the condition of her intestinal tract. Many patients with recurring attacks of so-called cystitis suffer from diseases of the gastrointestinal tract, such as cathartic colitis, spastic colitis, constipation, hemorrhoids and amebiasis. Therefore, this possibility must be ruled out. Last, but not least, is the significant statement that these attacks of cystitis follow intercourse. This is significant in view of other statements that everything else has been normal. If results of the genitourinary examination, the gynecological examination and the examination of the intestinal tract are all negative, there probably is a psychic element in this case, and she should consult a psychiatrist. It would be interesting to know whether sexual intercourse was painful. This clinical picture is not so uncommon.

LOW SPERM COUNT

To the Editor:—*What effects, if any, have cathode rays or any other rays present in certain departments of television companies? A healthy married man in his twenties, who is the father of a 4 year old child, born when he was a milk driver, now has a sperm count of only 6,000,000, with 50 per cent motile (high power field) and 8 to 10 pus cells. There is no history of gonorrhea. If these rays have no effect on spermatogenesis, what, if anything can be done to stimulate sperms? The wife is normal but has not become pregnant again. Workmen at this television company are of the opinion they are being exposed to a certain amount of x-rays given off by the television sets.*

A. E. A. Wanderer, M.D., Oak Park, Ill.

Answer.—It is hardly likely that the amount of cathode rays associated with television machines can penetrate deeply enough into the body to produce sterility. Therefore, some other cause for the low sperm count should be looked for. Generally, the attempts to increase a man's sperm count are not very successful. Nevertheless, every effort should be made to try to increase the procreative ability of the man. The diet should be discussed with the patient, because occasionally an improper diet may be responsible for impaired fertility. Vitamins, such as A and E, have been prescribed, but an impartial analysis reveals that these have not helped much to stimulate spermatogenesis. Other vitamins have not been tried out sufficiently.

In the discussion with this patient, the matters of excessive amount of work, fatigue, marital troubles and other anxieties should be discussed. Every effort should be made to overcome tiredness, overwork, excessive use of alcohol and sedentary habits. If the patient is overweight, an effort should be made to reduce the excess.

Endocrine products are being used extensively to increase spermatogenesis. The following substances are in use: (1) thyroid extract, (2) chorionic gonadotropins, (3) pituitary gonadotropins, (4) mare's serum gonadotropins and (5) androgens. In patients with hypothyroidism, thyroid extract is of distinct benefit; otherwise it usually is not of much help. The results with the gonadotropins are far from good, and some men will have foreign protein reactions from these gonadotropins. The male sex hormones are used, but they may be without benefit and may actually depress spermatogenesis.

It must be realized, therefore, that at present there is no satisfactory hormone treatment for defective spermatogenesis, but improvement can be obtained in some cases. There is as yet no specific sexual hormone with which to increase spermatogenesis.

SUBSTANCES USED TO STIMULATE FIBROUS TISSUE

To the Editor:—*The answer to the query on this subject in* The Journal *June 2, 1951 (page 509) makes no mention of work by Boyd, Saint, and me on the treatment of thoracic and abdominal aneurysms of syphilitic and arteriosclerotic origin by the periarterial injection of dicetyl phosphate dissolved in olive oil* (J. Indiana M. A. 42:889 [Sept.] *1949). I discussed this subject before the Central Surgical Association in February, 1951, at which time I reported that 0.9% dicetyl phosphate dissolved in olive oil produced an enormous amount of fibroplasia when injected around blood vessels in experimental animals. The olive oil must be heated to body temperature in order to keep the dicetyl phosphate in solution.*

We recently received a supply of sodium dicetyl phosphate from the Monsanto Chemical Company. This is a tribasic salt with two hydrophilic radicles, namely, sodium and phosphate. This leaves the dicetyl component as a suspension which is easily injectable and does not require heating. Moreover, the strength of the solution may be greatly increased over that used in olive oil. Dicetyl phosphate has been used in the treatment of aneurysm in four patients. The results have been very promising. As soon as a sufficient time for proper evaluation has elapsed, a report will be made of the clinical results.

DIAPER RASH

To the Editor:—*In Queries and Minor Notes in* The Journal *(146:416 [May 26] 1951), a question is raised concerning ammonia dermatitis and its treatment with regard to possible agents given internally. This question was not directly answered, and no mention was made of oral preparations that could be used as prophylaxis or treatment. I would like to call attention to the article "Napkin Dermatitis Caused by Ammoniacal Urine: Treatment with Methionine" (Goldstein:* Arch. Pediat. 66:*553-560* [Dec.] *1949). This is a practical paper, and a theoretical discussion of mode of action is presented.*

THE PSYCHOLOGICAL MANAGEMENT OF CANCER CASES

Nathan S. Kline, M.D., Worcester, Mass.
and
Julius Sobin, M.D., Newark, N. J.

Improved methods of cancer detection and public education on the subject mean that physicians are seeing and treating many more malignant lesions than ever before. More widespread lay knowledge about cancer has almost resulted in a situation in which "every man is his own diagnostician." Formerly, cancer was almost unmentionable between patient and physician, and most persons did not wish to know nor expect to be told of such diagnoses. The pendulum has swung far in the opposite direction, and, along with its benefits, the educational campaign has resulted in an almost national cancerphobia. Our civilization breeds guilt feelings of one form or another in almost all of us; since guilt tends to seek out a "punishment" the cancer-education campaign has provided potential punishment for many persons.

In any case, the attitudes of cancer patients have altered significantly in the past 10 years, and not the least of the problems is the psychological management of these cases. In medical school lectures, it is generally customary in an outline of the treatment for virtually any chronic illness to list psychotherapy as the final item under treatment. Usually the elaboration of this point consists only of a suggestion to "help the patient adjust to his condition." The how's, why's and wherefore's are seldom discussed. Although each physician handles not only his cases in general differently but each patient somewhat differently from any other, it is felt that a general review of the problem may be helpful and suggestive.

TO TELL OR NOT TO TELL?

Unlike tuberculosis, where danger of contagion makes informing the patient of the nature of his illness practically mandatory, in cancer there is a distinct and sometimes painful choice to be made. Certain considerations are involved in making this decision.

1. The physician should be absolutely certain of the diagnosis. Until he is certain, any action that might arouse suspicion by the patient of the nature of his illness should be avoided. It is best even to dissimulate at this stage. There must be some appreciation, however, of the severity of the patient's symptoms. Unless it is impressed on the patient that the condition may be serious, difficulty may arise in having him follow through with the necessary diagnostic procedures. If he questions the necessity for these additional tests, a suggested approach would be "I want to make certain this is only lymphadenopathy" (or hemorrhoids or another condition). If subsequently the diagnostic procedures give normal results, the patient has been spared from severe psychic trauma, and, if the evidence shows abnormal conditions, few patients will not understand that the physician was attempting to spare them anxiety until he himself was certain.

Mention of disease should always be coupled with stress on the need for treatment: "The symptoms will become annoying or dangerous unless you follow through with treatment." When some patients learn that their illness is likely to be fatal they feel that treatment is useless. It must be emphatically pointed out to these patients that no illness is absolutely fatal, and that, with proper treatment, there is at least some chance that they will recover. That they owe the obligation to undergo treatment not only to themselves but to their families is worth stressing, if this reaction occurs.

2. Unless there are strong indications to the contrary, it is advisable to wait until the patient asks. With the widespread knowledge of cancer symptoms, it is inevitable that those patients who want to know will eventually present the physician with this opportunity.

3. The major consideration of the physician in deciding whether to conceal from the patient the nature of his illness should be the way he manages other life situations. It will probably be better for those persons who have a realistic approach to life in general to know the truth. To judge the realism of their general attitude does not require profound psychiatric training. The patient who in the past has inquired how much an operation will cost, how long he will be incapacitated, and the other "hard facts" is usually the realist.

4. If the patient does ask, the way he phrases his question may give a strong indication as to the type of answer he desires. The "I don't have cancer, do I?" phraseology is really only a request for negative reassurance and in all likelihood should be met with the tactics of evasion. Physicians have all had experience with the mother who asks about the possibility or the unlikeli-

hood of her child's becoming infected with some current contagious disease and when a realistic answer is given is horrified by even a small positive possibility.

If the Patient Is Told.—Regardless of how stable a person may seem, the psychological shock is certain to be severe. This can be "buffered" to some extent if the truth is told in easy stages. It is often desirable, for instance, when the patient inquires about the possibility, to discuss it purely hypothetically, even though the physician already knows that there no longer remains any doubt. Stress should be laid on the fact that therapy is available for even the most malignant of neoplasms. In some patients, statistics as to life expectancy and such facts as those presented by Finesinger,[1] showing that life expectancy for the general population would be increased less than two years if cancer were completely eliminated, may prove of value but is not a great consolation to most patients. The physician should be as honest as possible with the patient about his condition and try to get him to accept the illness as a fact rather than either a major disaster or an unimportant incident.

When the physician does reach the stage at which he is ready to tell the patient definitely of the nature of his illness, he should have available and visible concrete evidence, such as the pathological report, if possible, and x-ray report. It is probably advisable to interpret the results to him rather than to merely present him the pathological report. For a patient to read that there is a widespread malignant carcinoma is an unnecessary cruelty, since the same idea can be given with less of a shock by the interpretation of the physician. It is important to forestall the possibility of raising false hopes or of driving the patient to charlatans and quacks, who might question the diagnosis, if it has not been conclusively enough presented.

No matter how great the confidence that a patient has in his physician, he will probably take into consideration the possibility of his being in error. If at all feasible, at least the possibility of consultation with a colleague or a reputable specialist should be offered to the patient.

The patient should be advised that it would be desirable to get his affairs in order; but a definite date as to the likelihood of his death is extremely undesirable. Many a physician has hurt his reputation by saying that a patient has at most six months to live when, a year later, this same patient was contradicting this estimate. The advice should be given not as a death warrant but as a possibility for which it will do no harm to prepare. The question of the patient's plans for the disposition of his property and of his life insurance should also be raised although efforts should be made to avoid making this a focus of his attention.

Immediate reassurance should be given to the patient as to the nature of the therapeutic program, so that he will feel that everything is not hopeless and that everything possible is being done for him. Most patients associate cancer with excruciating and chronic pain, and it is certainly desirable to reassure the patient insofar as possible as to the extent of discomfort involved and the amount of relief that may be expected from analgesics if they are found necessary. When analgesics are used, there should be no hesitancy in their liberal application. The aim should be to prevent discomfort rather than to alleviate it. A combination of *d*-amphetamine sulfate (dexedrine®) and *dl*-amphetamine sulfate (benzedrine®) will often alleviate anxiety and depression.

For reasons beyond the scope of this article, it has been found that many patients with cancer develop a strong sense of guilt (cf. Nolan D. C. Lewis' aphorism, "Cancer is paranoia at the cellular level"), and, as much as possible, this should be alleviated. Many of these patients feel that the financial strain placed on their family is one of the most unbearable elements of the illness. A discussion concerning the extent of financial involvement and the means by which it can be minimized should be introduced, whether or not the patient raises the question. The physician should stress that he will keep his own part of the expense as low as possible.

Whether the family should be informed of the patient's illness and if so, how, should also be reviewed in detail with the patient. The major responsibility rests with the physician, however. It is unlikely that the patient has ever had cancer before, whereas the physician has had much contact with problems of this kind. It is the physician's responsibility to advise and counsel the patient and actively suggest the course he should follow. At a time of stress, it is a consolation to the patient to have present someone, such as a physician, who appears adequate to advise competently what should be done.

Unless there are strong indications to the contrary, the patient should be urged to retain his usual job as long as possible. A complete shift of activity before it is absolutely necessary appears to be extremely demoralizing. Even when the patient becomes partially incapacitated, he should be urged to carry on parts of his job that do not too severely tax him, even if only on a part-time basis. Auxiliary activities should be introduced at first as purely diversional, so they are not made to appear as childish and inconsequential substitutes for usual activities. If the patient will not be able to carry on his usual activities, he should be helped to plan as far as possible for substitute ones. If these can be developed and a real interest aroused in the patient before he is completely incapacitated for his regular work, a major therapeutic step will have been achieved. The nature of the substitute activities is naturally largely dependent on the character of the patient himself. Such activities as painting, radio contests, crossword puzzles, and stamp collecting are within the physical capabilities of all but the most incapacitated. The physician should be a pillar of stability, able to advise the patient at each step of the way.

If the Patient Is Not Told.—If it is found desirable to conceal from the patient the nature of his illness, it is usually wise to substitute some other condition. As the symptoms progress, the patient will inevitably know that something is wrong with him, and, if he is able to attribute it to some relatively benign condition, he will at least have the consolation of "understanding" the cause of his complaints. It is well to forewarn him that such discomforts are likely to occur. The nature of the condition substituted is dependent, of course, on the location and extent of the neoplasm and should not actually exclude the diagnosis of neoplasm. "A type of stomach ulcer," "a kidney blockage," "a liver dysfunction," is the type of equivocal diagnosis suggested. Here again emphasis should be laid on the fact that the condition may become serious unless properly treated. Unless the patient is sufficiently impressed with the fact that he must have treatment to avoid serious discomfort, he may tend to disregard treatment to a large extent, even when it might prove of distinct benefit to him.

---

[1] Finesinger, J., in Blain, D.: Elements in Motivation for Cancer Examination and Treatment, read at the annual session of the American Radium Society, Atlantic City, N. J., June 30, 1949, unpublished.

At times the cancer is not discovered until laparotomy is performed. In these cases, a diagnosis of "a certain type of ulcer" or "one type of bowel block" can be offered, and removal of the offending organ deferred on the basis of there being "a slight infection," which must be treated first. This will even provide a reason for rehospitalization of the patient if he becomes so debilitated that it is necessary. The physician should exercise great care not to reveal the truth inadvertently, and it may even be desirable to carry a euphemism on the patient's chart or office record. Office personnel should also be trained to be noncommittal and discreet (outside as well as inside of the office) and, in general, to be optimistic and helpful.

Occasionally, a patient who you feel would be better off not knowing will ask directly whether he or she has cancer. Except in rare instances, it is hazardous to answer with an outright denial. Eventually, the majority of patients who really want to know will discover the truth, and if you have deliberately lied to them, they will lose confidence in the real reassurances and consolations that you could offer. It is better to avoid answering at all than to present the patient with a direct falsification. The major problem in the handling of those patients who are not told their diagnosis is the management of the family, which is discussed later.

Management of Family If They Are Told.—If the patient has been informed of the nature of his illness, he himself should be the major judge as to who should and who should not be told. The way in which the family is presented with the facts should also be decided on by the patient himself. It is again the responsibility of the physician to suggest to the patient ways and means of presenting the facts. The patient should be strongly urged to bring into confidence at least one responsible member of the family, although this need not be the nearest relative. It will probably be necessary to impress the family at least to some extent with the seriousness of the patient's condition, so that they will be cooperative. Although the seriousness of the illness should not be minimized and the unsuitability of such an occurrence not overlooked, still the advantages of knowing the truth can be contrasted with the consternation of unexpected death.

Most of the "don'ts" connected with the behavior of the family are rather obvious. Frequent and tearful commiserations are certainly undesirable, but false cheerfulness is probably even more disturbing. When all concerned realize the seriousness of the situation, obviously unmeant gaiety strikes an extremely jarring note. The most desirable attitude on the part of both the family and the patient is acceptance of the fact as such, with an effort to expend the remaining time as constructively as possible. Finances should be discussed with the family, and, even though prognosis is poor, the moral obligation of the family to follow through with whatever treatment is available should be emphasized.

The family should also be cautioned to avoid discussions with the patient involving plans contemplated at a time when the patient will no longer be present to participate even vicariously. This does not mean that concurrent activities should not be entered into. The patient already feels left out of things, and, unless he protests, he should be allowed to participate, at least at second hand, in what is going on.

Also to be strictly avoided are regrets, recriminations, and "might-have-been's." If the patient falls into this type of mood, an effort should be made to turn the discussion toward more neutral subjects rather than end it abruptly with "let's not talk about that." The family should encourage the patient to continue at his regular job as long as possible but should begin to interest him in substitute activities. He should be encouraged in his hobbies and in occupational therapy. Again, too much enthusiasm may be detrimental. Praise is in order for those things that the patient does accomplish, but it should not be too much beyond the real merits of the work. If the patient is partially incapacitated, he should be made to feel as useful as possible. He should be encouraged to do as many useful things as he can, e. g., he might make minor repairs or telephone food orders.

As much time as possible should be spent with the patient. This does not mean that a constant conversation need be maintained. Simply sitting in the room reading or listening to the radio provides the human contacts that most persons need during a crisis of this kind. Whether the patient should have many or few visitors should depend in large part on his former mode of existence. This should be kept as nearly normal as possible. As a rule, close friends should be encouraged to visit, but emotional, unstable persons, whether relatives or friends, should be excluded as far as possible.

In some cases, when the family has knowledge and the patient has not, the patient himself exerts much pressure to find out "what the doctor said." At times, strong guilt feelings may be created in the family if they have to tell deliberate lies, and sometimes the situation can be helped if the statement to the family is worded in an equivocal manner; however, it should still be clear. "I will not say what disease the patient does have, so you can honestly tell him that I have not said he has cancer, if he asks." "I have told the patient that he has such and such a condition, since his symptoms in part resemble this disease. I am not telling you that he has cancer, so you can be perfectly honest in denying that I said he has cancer, if he does insist on knowing what I say." It is surprising how helpful such a wording of the diagnosis can be to relatives.

Since cancerphobia is already widespread, the occurrence of cancer in a member of the immediate family may activate a large amount of anxiety, and it is wise to offer the possibility of a complete physical examination to other members of the family, to allay their fears.

If the Family Is Not to Be Told.—Unless it is specifically requested, it is probably preferable not to volunteer any information as to the patient's condition. In some cases the family has no desire to know the progress and it is not unlikely that they may never specifically inquire. In reply to insistent questions concerning the nature of the patient's illness, when they can no longer be deferred, the matter should be discussed with the patient, if he himself knows, and consideration given to whether it is wise to inform the family. Here again, the physician should act as adviser to the patient. It may be easier for him to tell the family than for the patient to do so, which may also allow the patient and his family to avoid discussing the illness, which may lessen the tension. In telling the family, as in dealing with this matter with the patient, the physician might use some euphemistic substitute.

When the physician is questioned as to the patient's progress, he may give such answers as "He is getting along as expected" or "He is doing well, all things considered," which are usually satisfying and do not put the physician in the position of stating outright untruths.

If no one in the family is found to be responsible enough, either emotionally or otherwise, to be told the plain facts of the case, a medicolegal problem exists. It is wise in these circumstances for the physician to protect himself by having a colleague called in as consultant who can concur in the decision of the physician and the patient to withhold knowledge from the family. If a question later arises, there will be adequate evidence that this was the patient's decision.

GENERAL CONSIDERATIONS

If the patient is considered inoperable, the relative value of hospitalization in relation to benefits to be obtained should be discussed with the patient, if he is told, or the responsible member of the family if the patient is not told. The physician should suggest what seems to him the most feasible plan. In many of these cases, home care is psychologically more beneficial and provides the patient with more pleasant and active surroundings than would be the case if he were hospitalized. In other cases, it may help both the family and the patient if he does not have to remain at home and be constantly reminded of his "tragedy." The strain on the family, both physically and emotionally, should be carefully weighed. The reassurance that something is being done when the patient is hospitalized must be weighed against the fright that may be aroused by prolonged hospitalization.

TYPES OF REACTION TO KNOWLEDGE OF CANCER

It is most desirable, of course, that the patient accept the fact of his disease and that he plan the remainder of his life accordingly; however, at times, when the diagnosis is beyond question and can be substantiated by laboratory and x-ray reports, the patient refuses to believe the inevitable facts. He may then resort to visiting a great number of other physicians. This provides a hope of escape and, as previously mentioned, the physician should anticipate this by suggesting other consultants if the patient has any desire for independent opinion. It is probably even advisable for the patient to be seen by a consultant before the physician gives his own final decision. At times, even two or three other opinions do not satisfy the patient, and he persists in a futile search for someone who will deny the existence of his condition. Anxiety and severe depression usually arise when someone is in an unpleasant position and there are no active steps he can take to relieve the tension. Visiting large numbers of physicians may at least provide activity that, although fruitless, may alleviate the pressure.

The greatest danger in cases of patients who refuse to accept the diagnosis, when it has been felt desirable to tell them, is that, instead of seeking reputable medical assistance, they become victims of various charlatans. If the patient cannot be convinced of the validity of the diagnosis, it is important to maintain a good enough relationship with him to prevent his falling into the hands of unscrupulous persons who would exploit him. The physician should not react to a refusal to accept an obvious diagnosis by feeling that a direct assault has been made on his medical integrity. Some persons find visiting physicians a useful escape device; although the physician should not encourage it, it may be considered psychotherapeutic. However, the patient should be prevented from falling into the hands of quacks.

Occasionally, even though the patient has been unequivocally told what his diagnosis is or has been presented the facts in such a way that the conclusion is obvious, he fails to grasp the truth. Some physicians may feel guilty that they have not made the matter sufficiently clear. This kind of rejection of the diagnosis by the patient is essential for his psychological health. If the patient does not want to know the diagnosis, the matter should not be forced.

Flight from the Disease.—At times patients will become actively psychotic and lose touch completely with reality. The management of patients of this type is naturally for the psychiatrist. A prompt referral without unnecessary temporizing should be made. Other patients will develop compensatory outlets, the most frequent of which is turning to "religion." As long as the patient can develop and exercise his new-found "truth" without interfering with his medical treatment or injuring himself and his family in other ways, he should be encouraged in this activity. It would be surprising if the prospect of decreased life expectancy did not result in some such reorientation. The intensity of previous religious beliefs may be increased, or there may be a devoted adherence or belief in the importance of almost any "cause" or theory. At times the new belief is radically different from the patient's former views. If the new "religion" is likely to cause a severe financial or emotional drain on the family, the problem is complicated. While the main theme of the belief should not be destroyed, it is often possible to turn the patient's expression of it into less devasting channels. Instead of allowing him to give a major part of his estate, which may be needed by his wife and child, to "The Society for Motherless Cats," the physician should try to get him to substitute such activities as bringing the matter to the attention of the public in the newspapers or writing to persons with similar beliefs.

Another form of flight from the disease is suicide. In most cases, this is more verbal than actual. There does exist a real possibility, however, in almost every case, and it is the physician's responsibility to guard against this, insofar as possible. The stigmas of incipient self-destruction cannot be detailed in full within the scope of this paper, but it is important to note a sudden, complete acceptance of the situation following prior difficulty in adjustment, history of depression earlier in the patient's life, and insomnia, depressed posture, and anorexia, occurring without adequate organic basis. It is advisable to see the patient daily until it is certain that his emotional state is such that there is no great suicidal risk.

Occasionally, a patient will respond with euphoria to the knowledge of a fatal disease. As a rule, this condition wears off and should always be regarded as a compensatory type of reaction covering a severe depression. The euphoric patient is often a greater suicidal risk than one who is openly depressed. This type of reaction is basically emotional in origin, and it is not advisable to argue with the patient to convince him of the seriousness of his condition. In some cases, a mild *belle indifference* continues and may well constitute a satisfactory reaction to the situation. By accepting the real fact intellectually but not emotionally, the patient may be able to protect himself against catastrophic inner turmoil.

Overreaction to the Disease.—At times knowledge of a chronic fatal illness may result in complete physical collapse, and hospitalization becomes necessary, not so much for the treatment of the chronic illness as for building the patient up to some sort of functional level. Patients of this type should be treated with much affection and consideration by both physician and family. If they return to a pseudoinfantile state, they should be handled in many respects as children.

Severe and prolonged depression with or without suicidal tendencies may result when the facts of the condition are made known. A certain amount of depression can well be considered normal, but if this persists, it should be treated. Electric shock therapy, regardless of its ultimate merits in the treatment of the more serious mental illnesses, is almost specific for reactive depressions of this particular type. There are few medical conditions, except metastases to lung or bone (where there is resultant danger of hemorrhage or fracture), that preclude the use of this type of treatment, which, if necessary, can even be given in the home. Usually, six treatments will relieve the extreme elements in the depression.

Obsessive Preoccupation with the Disease.—That a patient with this condition will dwell on it to some extent is to be expected. As previously outlined, efforts should be made to divert him from this type of preoccupation. In cases in which this is unsuccessful and the patient's preoccupation becomes so severe that he makes life intolerable for both himself and his family, serious consideration should be given to one of the psychosurgical procedures. In addition to relieving intractable pain, prefrontal lobotomy usually results in the loss of this preoccupation with self and future, which leads some chronically ill patients to suffer out of all proportion to their illness.

Other techniques, such as hypnosis and intensive psychotherapy, are valuable in some cases.

and
Benjamin H. Kesert, M.D., Chicago

About 300 veterans suffering from injuries to the spinal cord and cauda equina are in constant residence in the medical wards of the United States Veterans Administration Hospital at Hines, Ill., under the care of the Medical Neurological Service. In addition, the Neurosurgical Service is responsible for patients with current acute injuries and those with old injuries who need surgical treatment, such as rhizotomy, exploration, or chordotomy. Patients requiring these procedures are transferred to the latter service, which has available an additional 75 beds.

ORGANIZATION

Staffs are appointed and treatment is operated under the Deans' Committee plan. In this plan, the attending and consulting staffs are appointed from the faculties of the medical schools in the Chicago area. It so happens that the staffs in neurosurgery and medical neurology are members of the faculty of Northwestern University Medical School. Under this plan, in addition to the regular staff of the United States Veterans Administration, residents in training also act in a capacity analogous to that of ward surgeons.

In planning the organization of the treatment of patients with wounds of the spinal cord or cauda equina, it was decided that injuries, as well as diseases, of the nervous system were properly the responsibility of medical neurologists.

Consultants in neurosurgery, general surgery, orthopedic surgery, plastic surgery, genitourinary surgery, medicine, and physical medicine are appointed to this service. Each is responsible for his particular specialty. Not only do these specialists serve when called into consultation in a particular case, but it is their responsibility to study the relation of their specialty to the problem of the treatment of these patients and to devise the best means of prevention of the complications within their specialty and their most efficient treatment, and then, on consultation with the Department of Medical Neurology, to put these methods into effect.

Read before the Section on Nervous and Mental Diseases at the Ninety-Ninth Annual Session of the American Medical Association, San Francisco, June 30, 1950.

Assisted by a grant from the National Research Council, Division of Medical Sciences, Committee on Veterans Medical Problems, acting for the Veterans Administration.

From the Department of Nervous and Mental Diseases, Northwestern University Medical School, and the Department of Medical Neurology, Veterans Administration Hospital, Hines, Ill.

Sponsored by the Veterans Administration and published with the approval of the Chief Medical Director. The statements and conclusions published by the authors do not necessarily reflect the opinion or policy of the Veterans Administration.

This plan has operated admirably since 1946. Many studies have been made upon special aspects of the problem. Among them have been studies on spasms, spasticity, and reflex activities; pain; dysregulation of temperature; reflex hypertension; orthostatic hypotension; sweating; dysregulation of water metabolism; bladder and rectal function; nutrition and bodily function; orthopedic, surgical, neurosurgical, and genitourinary surgical problems; problems of physical medicine, and the follow-up observation of discharged patients by social service. In addition, analyses are made of the pathologic changes found in case of death of any of the patients.

From these studies and the observations and experience of all the consultants and physicians, certain conclusions have been reached about broad principles of management. It is not intended in this article to describe medical or surgical procedures, to compare one method with another, or to hold a brief for any favored devices. Such descriptions have been made before upon numerous occasions.

It is our intention, rather, to relate the conclusions reached by us in respect to basic principles, as may have been indicated by our experience. Our conclusions are derived from our experience gained from the treatment of the whole material, 767 patients, as well as from more intensive studies on smaller groups or patients selected for investigation of some particular subject, such as pain or spasms.

In a comparison of the evolution of signs and symptoms and of complications of injuries of the spinal cord and cauda equina sustained in civilian practice before the war with corresponding data on patients injured during the war and later treated under the oft unavoidable adverse conditions of military practice, many differences could be found in relation to mortality, morbidity, and complications.

Munro [1] took advantage of his many years of study and attention to injuries of the spinal cord when he compared his extensive experience in civilian experience with his later observations on the residuals of injuries to the spinal cord and cauda equina resulting from war wounds after treatment in military practice and final residence in the United States Veterans Administration hospitals.

To those of us who had not had extensive experience with injuries of the spinal cord and cauda equina in civilian practice, such a point of comparison was unavailable. However, since the end of the war many veterans have sustained injuries to the spinal cord and cauda equina and either have been treated immediately in civilian hospitals and transferred soon thereafter to the United States Veterans Administration hospitals or have been taken immediately after injury to such a hospital. By a comparison of the evolution of signs and symptoms in this group with that of similar signs in men injured overseas during the war and first treated in military hospitals, a similar study was made possible. The results of this study led to parts or the whole of some of our conclusions. In addition, certain special studies led to conclusions as to the site of origin of distal burning pain; the evolution of pain; the evolution of spasms, spasticity, and reflex activity; the evolution of decubitus ulcers, of genitourinary and bowel function, and of recovery after injury; changes in the physical bodily state; evolution of genitourinary complications and the result of their treatment by a program of physical medicine; follow-up observations after discharge of the patient, and pathologic changes found after death.

PAIN

From our discussion of pain we shall exclude that type which is referred distally from lesions of roots at the level of injury, since the treatment of these lesions, as in the case of tabes and other diseases producing root pain, is well known. We shall discuss only that pain which occurs below the level of the lesion, which is diffuse, often imperfectly localized, and is described by such words as burning, tingling, stinging, aching, pins and needles sensation, or sharp and shooting. In other words, it partakes of the character of a paresthesia much more than that of a simple pain. In 80% of the patients with this type of pain the word "burning" is considered most fitting to describe it. The localization of this pain is often inconstant in a given patient, and the pain usually is felt diffusely in such areas as the soles, both lower extremities, the abdominal wall, or the lower half of the abdominal wall only. Relatively soon after the injury the pain is sufficiently intense that the patient spontaneously complains bitterly and asks for relief. To relieve this, drugs, including narcotics, have been used freely, often ineffectually, and frequently to the point of producing addiction. Because of this, surgical procedures have been performed with the purpose of interrupting neural pathways that transmit painful stimuli to the brain. The two most commonly performed procedures have been section of the posterior roots and of the spinothalamic tract within the spinal cord, and chordotomy. First, we wish to report upon our conception of the site of origin of this pain, to the end that certain surgical procedures will be made immediately to appear potentially ineffectual in any way.

To explain such pain, many theories have been advanced. Practically all call upon the intermediation of the sympathetic nervous system.

It has been observed by us in a number of cases that when, in the presence of an injury of the spinal cord, a limb may have been amputated at the thigh, the patient not only seems to feel the existence of the amputated lower extremity and describes its position, but also suffers from the same burning pain that he experienced before, and that is present in the remaining limb. This indicates immediately that there can be no centripetal impulses from the amputated limb which can give rise to such sensations.

In cases in which the spinal cord has been injured and a spinal-fluid block is present, we have found that with spinal anesthesia below the level of the lesion, interrupting centripetal fibers through the posterior roots into the spinal cord, this diffuse burning pain is unaffected. On the other hand, when, in the presence of the spinal-fluid block, the distal end of the proximal segment of the injured spinal cord is anesthetized by spinal anesthesia, the pain disappears. To us this indicates that the site of origin of the pain is the distal portion of the proximal segment of the injured spinal cord. Therefore, posterior-root section and any operation upon the sympathetic nervous system would be futile.

---

[1] Munro, D.: Rehabilitation of Veterans Paralyzed as the Result of Injury to the Spinal Cord and Cauda Equina, Am. J. Surg. 75: 3, 1948.

There remains to be considered the advisability of chordotomy. Chordotomy performed by trained and qualified neurosurgeons is associated with no serious danger of complications; but chordotomy performed by inexperienced surgeons, often untrained in neurosurgery, is a dangerous procedure indeed. If it were assumed that a patient having complete paralysis of motion and loss of sensation below the level of the lesion was doomed to remain in that state during the rest of his life, it would make little difference whether the level of his lesion were to be raised to one a little higher in the thoracic portion of the cord. However, as will be shown, some recovery of motion and sensation, or of one alone, may occur when for many months a complete interruption of the spinal cord has been assumed to be present.

Even if the recovery does not result in useful motor function, it is associated with beneficial effects, such as the healing of decubitus ulcers, lessened incidence of later-developing decubitus ulcers, and improvement of bladder, bowel, and genital function.

For these reasons, the indications for chordotomy must be assessed very carefully. In our series, 16 patients have been subjected to chordotomy from one to three times each, with a total of 23 operations for the group. In only two patients was chordotomy followed by complete and permanent cessation of all types of pain. For both, two operations were required to achieve this result. In five patients six chordotomies produced no effect whatsoever on the preexisting pain. In the remaining nine patients, the procedure produced temporary relief, or relief from only one type of pain present (usually root pain) and not from other pain, or the operation was actually followed by an onslaught of pain that had not existed previously.

What is the life history of this pain? In 1947, in a high incidence of cases, in fact, in 82%, this pain was noted as a spontaneous complaint. At that time, in many instances it seemed severe enough to warrant active therapy. As time passed, this type of pain receded from consciousness, and its presence was elicited only on direct questioning. Thus, of 217 patients, it was spontaneously complained of by 20%. In some cases it had diminished in severity as well, so that even when attention was directed to it the description of the pain indicated its lessened quality. At present, it is rare to find a patient with severe distal pain of this character, and there exists only a well-repressed awareness of easily borne distress.

Many times we have been gratified to find that the postponement of surgical measures to relieve pain was justified by the development of this high threshold for the pain. It is our conclusion that for distal "burning pain" posterior-root section and sympathectomy are contraindicated, since the site of origin of the pain is in the distal end of the proximal segment of the injured spinal cord. Because such pain in time both diminishes in severity and recedes in consciousness, chordotomy should be postponed as long as possible, and resorted to only in exceptional cases. It should be permitted to be performed only by experienced and qualified neurosurgeons.

SPASMS

The word is usually used loosely to denote involuntary movements of the extremities. Included in this definition are the pseudospontaneous spasms and the reflex movements which follow known stimulation, usually of the extremities. In the former case the motor movements are usually bilateral and symmetrical; in the latter, they are unilateral and may be followed by contralateral movement. Rarely are they symmetrical and bilateral. The patient is unable to distinguish between them, and the information obtained from patients who have not been observed from the beginning of injury probably includes both. Therefore, estimates of frequency, etc., vary in accordance with the source of information. Fortunately, the life histories of the two types are similar; this is not strange, since pseudospontaneous spasms result from stimuli, but they are usually midline stimuli, and often visceral, such as a full bladder or rectum. The spasms are also evoked by stimuli from sacral decubitus ulcers, handling of the genitals, and movement of catheters.

These spasms constitute a serious disability not only in evoking discomfort, but in interfering with healing of bedsores, genitourinary care and rehabilitation, and, rarely, in leading to dislocations and fractures. No medicament has been found of any real value, despite reports elsewhere to the contrary.

Therefore, section of the obturator nerve, and rhizotomy, usually anterior, less frequently posterior, have been resorted to. If the rhizotomy is successful in either case, the increase reflex activity is abolished. However, once anterior rhizotomy is performed, the patient can never have any useful return of motion.

With rare exceptions, for some time after injury, the patient has complete paralysis of motion and sensation. Later, recovery may occur at variable periods, and useful recovery has been seen when it began as late as five months after injury.

Since we have found that actual recovery, in some instances fairly useful, occurs in 21% of cases, great caution should be exercised in deciding that a rhizotomy should be performed. Not only is there indication for caution because of the possible recovery, but the life history of these spasms also emphasizes it.

First, the incidence of the spasms varies in relation to the segments affected, although succeeding analyses vary with the particular group. They all indicate that 60 to 70% of all patients with spinal-cord injuries have these spasms and that they are present with all cervical lesions of the cord, with 75 to 85% of thoracic lesions, with 31 to 44% of lumbar lesions, with 30% of lesions of the conus and cauda equina, and, of course, not with lesions of the cauda unless complicated by chordotomy.

They begin, increase, reach a peak, which is maintained, and then, in a great number of cases, diminish in severity, if not in frequency. In 71% of all cases they diminished in severity. During the early period of caring for the patients, the severity of the spasms was sometimes so great that a considerable number of the men were tied to the bed, chair, or frame. It is rare now to see a patient with spasm which seriously interferes with treatment or activities, and, of course, none need be restrained. Only 18 rhizotomies have been performed among the 589 patients, most of these being done before the patient's admission to the Hines hospital. Judged by whether there was an increase in rapidity of rehabilitation, or in degree, as measured by the Department of Physical Medicine, the results were not favorable in most cases.

With the Department of Neurosurgery, we early agreed that unless the lesion was proved to be anatomically complete, rhizotomy was to be done only on rare occasions, when it would be a life-saving procedure. We have not regretted that decision.

We believe that by adequate treatment of bladder and bowel dysfunction and by healing of bedsores, we have been able to bring about a diminution in the severity of these reflex movements.

DECUBITUS ULCERS

There is no uniformity of opinion as to the cause of decubitus ulcers, or so-called trophic ulcers. By some they are considered to be solely neurogenic; by others, solely traumatic. The truth probably lies somewhere between these two extremes of thought. That these so-called trophic ulcers are related to a dysfunction of the nervous system is almost self-evident.

The amount of trauma to the limb on the side of a unilateral experimentally produced section of the sciatic nerve, which resulted in numerous ulcerations of the foot, was in our experience no greater than that to which the control limb was subjected. With peripheral nerve lesions in man, although ulcers appeared only when the part was traumatized, they developed only in areas of defective sensation. Despite total paralysis of the lower extremities as the result of anterior poliomyelitis and the accompanying pressure and immobility, ulcers are indeed rare. On the other hand, in syringomyelia and tabes dorsalis they are common.

If the loss of sensation in spinal-cord injuries resulted in less frequent change of position, and this produced more continuous pressure on a part and was the full explanation of pressure sores, these lesions should develop as frequently late after the injury as soon after it. This was not the case. Severe sacral decubitus ulcers were the first to be observed in large numbers; then, after a time, when the patient was able to turn from side to side or was turned on his side, trochanteric ulcers appeared, and when, finally, he sat in a wheel chair or was driven about ischial ulcers appeared. Because of this, the definition of the early occurrence of ulcers differs with respect to the time allotted to this period. We defined early sacral ulcers as those occurring within the first month, early trochanteric ulcers as those occurring in less than two months, and early ischial ulcers as those occurring in less than six months. Of 89 patients studied intensively, sacral decubitus ulcers had developed in one month or less in 59.2%; trochanteric ulcers, in less than two months in 24.7%, and ischial ulcers, in less than six months in 8.6%. On the other hand, sacral decubitus ulcers had developed after one month in 12.1%; trochanteric ulcers, after one month in 23.5%, and ischial ulcers, after one month in 29.7%. It is evident that in our definition of early trochanteric and ischial decubitus ulcers too short a time was allotted. However, the sacral decubitus ulcers illustrate the point that by far the greatest number develop in less than one month. It is well known that deep necrotizing ulcers, destroying tissue to the bone, may occur during the first week after injury. Another indication of a neurogenic factor is seen in the distribution of ulcers at various levels, being 100% with lesions of the cervical portion of the cord, 100% with lesions of the first to the ninth thoracic segments, 84% with lesions of the 10th to the 12th thoracic segments, and 80% with lesions below the first lumbar segment. A further indication is found in the fact that of 83 patients with complete physiologic interruption of the spinal cord, ulcers occurred in 75, or 90.5%, and of 93 patients with incomplete or recovering lesions, ulcers occurred in 71, or 76.5%.

Still another indication is found in the fact, in part referred to, that the longer the time after injury, the smaller the percentage of ulcers. Thus, of 300 cases, the incidence of ulcers which developed before the first year was 90%; the incidence of ulcers which developed one to two years after injury was 65.1%; the incidence of ulcers developing two to three years after injury was 60.4%, and the incidence of ulcers developing three to four years after injury was 40.8%. Not only was the incidence related to time of onset, but the number of ulcers per patient diminished as the time between injury and development of ulcers increased. Thus, in intervals of the same sequence as those noted above, the average number of ulcers for each patient was 2.78, 2.74, 1.74, and 1.6.

Another indication is found in the comparative incidence of ulcers in patients in whom pain and temperature sensibility had partially recovered early after injury. Of 64 such patients, 14, or 22%, had ulcer at some site, whereas the incidence of ulcer in patients with complete interruption of the cord was 90%. In only two patients did decubitus ulcers develop at the Veterans Administration at Hines when recovery of pain and temperature sensibility had partially been accomplished.

In view of all these correlations, we believe that there is an important neurogenic factor in the development of ulcer. This is, of course, not the only factor, as shown by the fact that, although the population of the patients with injuries to the spinal cord is increased by new admissions and depleted by discharge of older patients, the incidence of ulcer and the number of ulcers per patient have steadily decreased since 1946. Thus, in 1946, 75% of patients had ulcers, with an average of 3.4 ulcers per patient; in 1947, 40% of patients had ulcer, with an average of 2.8 ulcers per patient, and in 1948, 25% of patients had ulcer, with an average of 1.9 ulcers per patient. This decrease occurred despite the inclusion of a number of the old ulcers in the material, for which surgical results were not as successful. Another indication of the possible prevention and spontaneous healing of early changes which later would perhaps lead to severe ulcers is found in the comparison of the percentage of patients in whom ulcers developed in other hospitals, where they were treated for the first six months after injury, and the number admitted to the Veterans Administration Hospital, Hines, Ill., less than six months after injury in whom ulcers developed. Of 67 patients received at the Hines hospital, 73% had sacral decubitus ulcers; 40% had trochanteric ulcers, and 4.4% had ischial ulcers. Fifteen per cent of patients were without ulcer. Of 32 patients admitted directly to the Veterans Administration Hospital at Hines, sacral decubitus ulcers developed in 3.3%.

The problem of bedsores in patients with lesions of the spinal cord and cauda equina presents a different picture from that seen in 1946 and 1947. In 1947, when the intensive effort to treat existing ulcers was well under way, about 30% of the patients with ulcers had rather extensive, undermined, and necrotizing lesions, usually in the sacral and trochanteric areas. At present, except in newly admitted patients, such extensive ulcerations are no longer observed. The ulcers now found are smaller and are usually not widely undermined. This is probably the result of careful inspection of critical areas by the patients themselves and by hospital personnel. The patient, as a rule, has sufficient information to understand the early signs of impending ulceration, such as persistent edema and abrasion. The patient and the hospital personnel are eager to prevent actual ulceration and to report such signs, the prompt preventive treatment being fully expected and actually received.

During the second world war, and immediately after the cessation of hostilities, numerous extensive ulcerations were accepted as an unavoidable exigency of war, but now the admission of one or two patients with signs of evident neglect produces consternation.

During the last two years an organized and closely checked effort has been made to determine the efficacy of conservative treatment of decubitus ulcers. The ulcers are measured every week and are dressed frequently in a properly equipped room by personnel trained in the technique of applying satisfactory dressings. All types and sizes of ulcers have been treated. The following agents have been applied or used: (1) soap and water, (2) hydrogen peroxide, (3) ultraviolet radiation, (4) zinc oxide ointment, (5) nitrofurazone (furacin®) ointment, (6) sulfathiazole ointment, (7) iodochlorhydroxyquin U. S. P. (vioform®) ointment, (8) petrolatum U. S. P., (9) thimerosal N. F. (merthiolate®), (10) bacitracin ointment, and (11) chlorophyll ointment and liquid.

The least effective agent was found to be sulfathiazole, and the most effective agent is generally agreed to be chlorophyll ointment and liquid. Of the ulcers treated conservatively, 23 per cent healed.

Ulcers presenting no tendency to heal under conservative treatment are operated upon. The operation usually entails the radical excision of the ulcer, including the underlying bone, and closure by primary approximation or by rotation of flaps and skin grafting. Ninety-six per cent of the ulcers operated on healed successfully. In 6% recurrences were noted in the surgical patients who were discharged from the hospital and who had to return. The causes of recurrence are believed to be as follows: carelessness on the part of the patient; trauma, such as may result from accidental friction and abrasion during falls, getting in and out of bed, automobiles, chairs, and other implements used in daily living; prolonged sitting; cross-country trips; unsuitable and ill-chosen labor activities, and associated alcoholism. A large percentage of recurrent ulcers healed under conservative hospital management. There is no evidence at present that intercurrent disease itself is associated with excessive formation of ulcers.

BLADDER

The most disastrous consequence of injury to the spinal cord in respect to mortality is the inability to urinate normally and the consequent infections of the genitourinary tract, leading to disease of the kidneys and uremia.

In the majority of cases the immediate consequence of injury was retention of urine or paradoxical incontinence, whether due to a spastic sphincter or paralysis of the detrusor muscle. Incontinence was present with only 5.5% of lesions of the first to the sixth thoracic segments, with 4.2% of lesions of the seventh to the 12th thoracic segments, and with 5.5% of lesions of the first lumbar segment and below.

The immediate treatment, as determined from a study of 199 patients, consisted of suprapubic drainage in 61, or 30.6%; of drainage by use of other continuous indwelling catheter in 86, or 43.3%; of intermittent catheterization in 29, or 18.1%, and of tidal drainage in 17, or 8.0%.

This distribution changed radically when definitive treatment planned for long periods was instituted. In April, 1946, when the patients at Vaughn General Hospital were transferred to the Veterans Administration Hospital, tidal drainage was being employed in 85% of the patients, and there remained only four patients with suprapubic drainage in 1947. A change in the function of urination had also occurred; as with reflex activities elsewhere, so in relation to urination, reflex activity of the bladder began and resulted in so-called automatic or autonomic function.

From a neurological standpoint, when a bladder, because of an increase in intracystic pressure, to an amount peculiar to each patient, resulted in reflex contraction of the detrusor and some emptying of the bladder contents, either an automatic or an autonomic bladder was stated to have developed. However, the development of such a reflex evacuation does not mean that it was adequate or that the patient by this means would avoid the necessity for forms of internal or external drainage. The amount of residual urine, the frequency of urination, or the susceptibility to infection under existing conditions led the urologist to define an automatic bladder in other terms, including almost complete emptying and no significant infection. This may be illustrated by a survey made by Dr. Benjamin Boshes in 1949, in which he found 80 cases of automatic bladder, whereas Dr. K. E. Barber found but 25 during the same year.

Automatic bladder function developed more frequently in patients with incomplete lesions (44%) than in patients with complete lesions (37%); of a special group of patients with recovering lesions it occurred in 51%. In 1947, when the material analyzed consisted of the older war injuries, an automatic bladder was found in 60% of patients. At that time some automatic function occurred with 38% of cervical lesions, with 62% of thoracic lesions, and with 70 to 75% of lesions of the lumbar segments, of the conus and cauda, and of the cauda equina. It appeared that the lower the lesion, the earlier the development of automatic function. This view was supported by the histories and interviews with 158 patients in 1950, when the range of time for its development with cervical lesions was 2 to 21 mo.; with thoracic lesions, 1 to 20 mo.; with lumbar lesions, 2 to 12 mo.; with lesions of the conus and cauda equina, 1 to 15 mo., and with lesions of the cauda, 1 to 9 mo.

Automatic function of the bladder is very capricious and can readily be disturbed, and even disappear, in the face of complicating genitourinary infections and other bodily disease and injury, and of hydronephrosis with high residual urine.

Only four of 29 patients with significant recovery of motion and sensation had recovered normal bladder function; of these, two had very good motor and sensory recovery, recovery being graded as ability to start the flow without abdominal compression, to empty the bladder and to stop urination at will. We found that no patient with any form of indwelling catheter could start urination, 80% of the 15 patients with automatic bladder function could feel or stop urination, but only two could start urination and 13% could start, stop, and feel urination, although not normally. Despite considerable recovery of motion and sensation, return of normal bladder function was rare.

It was early recognized that for the development of an automatic bladder, for training of bladder function, to insure sufficient activity for the patient's general welfare, and for treatment by a physical-medicine program it would be necessary to terminate any form of drainage as soon as possible. Such a plan was instituted.

Whereas in April, 1946, 85% of the patients studied intensively were on tidal drainage, in 1947 the figure was 29%; in 1948, 10.6%, and in 1950, 17.7%. However, the use of other forms of indwelling catheters became necessary as the result of genitourinary infections, fistulas, bedsores, surgery, intercurrent disease and injury, and hydronephrosis with high residual urine. In 1950, of a group of 158 patients studied, 33% had indwelling catheters, including those on tidal drainage and the Baumrucker program. In the three preceding years it was about 42%.

In 1948, about 50% of the patients wore some external device draining into a condom tube or other urinal. It was felt that these patients, including some with imperfect automatic bladders, were essentially incontinent, even if not continuously, and that under this condition they did not have residual urine, and therefore the procedure was less harmful than catheter drainage. However, improvement in the bladder function has increased, an earlier treatment of more recently injured patients has diminished the number in whom such devices are necessary, so that of 158 patients recently studied, 40% needed no device of any sort, whereas in 1948 only 4% needed none.

Although we had not been able to bring about that approximation to useful and safe function reported elsewhere, in addition to the changes in necessary impedimenta, some evidence of the success of management may be reflected from a comparison of the incidence of infections, stones, and necessity for cystoscopy. In 1946, 53.8% of the patients suffered from serious cystitis; in 1947, 48.8%; in 1948, 42.3%, and in 1949, 46.6%. In 1946 the mean number of infections per patient for that year was four; for 1947, three, and for 1948 and 1949 each, two. It must be remembered that new admissions of recent origin are being added to the colony. There were more cases of pyelitis in 1946; thereafter, the incidence remained almost the same. The same can be said of epididymitis and fistulas. In 1946, 35% of the patients had bladder stones; in 1946, 16.6%; in 1948, 16.3%; in 1949, 17.7%, and in 1950, 8.7%. The percentages for kidney stone were about the same. There were 224 cystoscopies in 1946, 118 in 1947, 88 in 1948, and 99 in 1950. (It may be of interest to note that 1,142 genitourinary surgical procedures were performed from April, 1946, to May, 1950.)

For psychological reasons, it had in former years been impressed upon the wounded veterans that they were disabled only by reason of their inability to walk and that otherwise they could be well and healthy men. This statement certainly is a deception. That it is a deception may be demonstrated from the results of autopsies. There have been 17 deaths among our patients; in 10 of these the cause of death was said to be uremia. In eight patients severe cystitis was found; in six, pyelonephritis; in nine, a pathologic condition of the kidneys including anemic infarct, nephrosclerosis (2), hemorrhage, acute contracted kidney, chronic passive congestion, degeneration of tubules, cloudy swelling, and subacute lipid nephritis; in one, abscess of the kidney; in three, amyloid infiltration of the kidney; in one, perirenal abscess, and in one, prostatic abscess and renal calculi.

This, of course, is not the whole picture, for in many instances, had not some succession of disasters to other parts occurred, the patient might have survived. Nevertheless, many die of disease of the genitourinary tract, and others, when the organism is insulted by disease or trauma, succumb to uremia, which in a normal man would not have occurred.

The development of an automatic bladder, bladder training, and the regulation of water intake, all are an important part of the management of spinal-cord injuries. Nevertheless, it must be remembered that "the bladder is a social convenience but the kidneys are essential for life."

Treatment of the neurogenic bladder produced by injury to the spinal cord cannot be described categorically. Even the general principles must be studied again and again before any uniformity of opinion may be brought about. Genitourinary complications succeed one another during the life of the patient, and one must be alert to them, to reexamine the patient at regular intervals even if other indications of disease do not manifest themselves, to change the method of management in accordance with the indications for a given patient or time, and, if the patient is to be discharged, to instruct him fully concerning his potential dangers and to put him in touch with a personal physician, hospital, or Veterans Administration hospital, so that early treatment for any complication may be instituted.

BOWEL CONTROL

As with the bladder, so with the bowel after injury to the spinal cord, voluntary emptying is impossible. This results in one of the very disabling sequelae of such an injury, not only in discomfort but in liability to infection of the bladder from bacterial contamination of bowel contents, and to injury. Regular periodic enemas were the rule after injury and were continued for a long period thereafter. Thus, in April, 1946, when the Veterans Administration assumed responsibility of the care of the patients, almost 100% of them were on an enema program. We soon felt that it was as important to bring about a state of automatic function of the bowel as of the bladder.

Immediately after injury, questioning of the wounded veterans elicited the information that 49% of those with cervical lesions had retention, and 51%, incontinence; 53% of those with thoracic lesions had retention, and 72% of those with lesions of the lumbar region or below had retention and 28% incontinence. These figures, derived from soldiers' statements, are misleading. The state of bowel action depended a great deal upon the consistency of the stool. When it was formed and by long retention became dehydrated and hard, "retention"—or, better, obstipation—occurred. When, for some reason, loose stools were present, as after catharsis, incontinence occurred; more extensive studies on the very early state are necessary before it can be said that a true retention occurs as frequently as is here reported. Since these reports deal with the early weeks after injury, tonicity of the sphincter, like tonicity of skeletal muscle, probably had not developed. It can be seen by comparing the tonicity of the external sphincter in the peace material with that in the war material, which consists of patients who had been injured a longer time before being examined than had the patients of the peace material, that a tonic external sphincter was present in 40% of the war material and in 80% of the peace material. With lesions of the cervical portion of the spinal cord, the external sphincter was spastic in both groups in about 90% of patients (in 87% of the peace material), with lesions of the lower thoracic region it was spastic in 30% of the war material and in 75% of the peace material. With lesions of the lumbar and lower levels, spasticity appeared in a smaller number, 23%. Some time after injury there is a relaxation of the tonicity of the external sphincter, and the condition differs from that originally seen.

As with the bladder, so with the bowel, some time later a reflex emptying may become possible. It becomes possible both with injuries of the spinal cord, in which a reflex contraction of the bowel musculature occurs and relaxation of the sphincter permits an evacuation, and with lesions of the cauda, in which an axonal reflex produces contraction of the bowel musculature and a patulous external sphincter allows the contents to escape.

Practically all the 244 patients studied in April, 1946, relied upon enemas for bowel evacuation. This necessitated a very large staff of attendants, who were kept busy, as in an assembly line, washing out the contents of the patients' lower bowel. The medical work on the ward was impeded; the morale of the patients was at low ebb, and an enormous quantity of supplies was necessary.

Aside from the patient's fear of soiling when traveling or on leave, the lack of confidence, the inconvenience and waste of time, and the time lost from healthful activities, the adverse effects of this program include the symptoms and signs and disturbance of other functions.

This is particularly true of patients with lesions in the cervical and upper thoracic portions of the spinal cord, in whom the increased autonomic reflexes result in hypertension, headache, profuse sweating of the face, chills, dizziness, and, in many, loss of consciousness. In addition, nausea, and at times vomiting, abdominal discomfort, anorexia, and increase of spasms and of burning pain were common to all levels of lesions. Moreover, in many patients disagreeable symptoms of ill-being persisted for one or more days, so that the patient was more or less continuously harassed by the results of the procedure. Accordingly, a program was instituted to teach the patient to accomplish emptying of the bowel first by reflex evacuation, with the later development of automatic function.

We already knew from a host of barium-meal studies that there was no impediment to the flow of barium as far as the large bowel. We also had learned from studying the appearance and retention of charcoal meals that there was a great delay in the passage of the stool along the large bowel, as well as the rectum, and that after the first appearance of charcoal a number of days could elapse before it completely disappeared from the stool. It was planned to develop reflex defecation first by stimuli designed to stretch the anus produced by the patient's finger, wearing a rubber cot.

It was found after much experimentation that, in order to initiate a successful bowel control program, lectures had to be given the attendants, nurses, and patients on the anatomy and physiology of the bowel. Demonstrations of gentle handling of the anal region and effective evacuation of the bowel following stretching of the rectal sphincter were given the attendants. This enabled them to start the method long before the patient could carry it out and facilitated the continuation of the bowel program while the patient was very ill or was recovering from operative procedures. The patient was also taught to use this method; his fear of an involuntary movement at home or in his car on the road was allayed, and he was convinced that incontinence would not occur. In those cases in which enemas had been taken for many months, there was at first a sluggish or no response to rectal stretching. However, as the tone of the rectal muscles returned, the patient noted greater ease in producing a bowel movement, and less time was needed to stimulate contractions. The patient was encouraged to use abdominal muscles, to strain moderately, or, if these muscles were paralyzed, to utilize manual pressure in association with the diaphragm to increase intra-abdominal pressure. As these manipulations became more efficient, many of the patients induced bowel movements merely by touching the area of the anus, and then gradually discarded the external stimulus as they acquired automatic defecation with the help of mild to moderate straining.

Except in one ward of about 50 patients, where the resident's chief interest at that time was the development of a bowel control program, in which the attendants and nurses cooperated with zeal, we were misled into believing that the program had been successful in 98% of patients. We have found out that in the other wards manual extraction had been resorted to in a number of cases without the knowledge of the ward physician. A more recent and enlightened investigation of 163 patients has shown that in 63% reflex bowel function has been effected. In 18% automatic bowel movements occurred. In 8% enemas were employed, and in the remainder manual extraction was resorted to. There is no doubt in our minds that the proportion of patients achieving reflex evacuation may be increased to 85%.

The time necessary to effect reflex evacuation varies. Of 16 patients with recent injuries, immediate results were obtained in seven when the injury had occurred two to four months before. For one patient eight months elapsed before it was effected, and for one, whose training began one month after injury, three months was required. With seven patients whose training began one to four months after injury, it had not yet become effective. A comparison of efficacy of training in war and in peace material in general suggests that reflex evacuation is easier to effect when longer periods since injury have elapsed, except in cases of injury of the lower thoracic and lumbar regions and below. The usual time for the war material was less than a month.

With the cervical injuries, it was effected in 75% of the war material and in 35% of the peace material; with injuries of the upper thoracic region, in 55% of the war material and in 25% of the peace material; with injuries of the lower thoracic region, in 55% of the war material and in 66% of the peace material, and with injuries of the cauda and conus and of the cauda alone, in 33% of war material and in 50% of peace material when the lesion was complete and in 100% when the lesion was incomplete.

Automatic bowel function occurred more frequently in the patients with considerable motor and sensory recovery. Of 13 such patients, four could start defecation. Of these, three could feel the passage of the bowel movement. This return of sensation is also present among some patients with automatic bladder function. None could interrupt defecation. As with the bladder, so with the bowel; very few achieve normal defecation, despite considerable motor and sensory return.

To change from use of enemas to automatic defecation may take only a few days, and this can be accomplished soon after the period of spinal shock.

The discontinuance of the enema management, although some patients resort to manual extraction, has been of great benefit to the patient and to the hospital. There has been a beneficial effect upon the morale of the patients; time has been freed them for useful occupation and treatment; appetites have increased, and all the complaints previously referred to have disappeared. For the hospital, it has made unnecessary the really tremendous number of linen articles and has made possible, along with other details of management, such as that of genitourinary complications, and bedsores, a considerable reduction in the number of attendants. Thus, in April, 1946 there were 179 attendants; in March, 1947, 140; in December, 1947, 130; in April, 1948, 120; in December, 1948, 113; in July, 1949, 106, and in January, 1950, 96. This decrease is related only to the lessened need for attendants.

RECOVERY

The potential recoverability of an injury to the spinal cord plays a part in the decisions concerning treatment and management of the patient.

Although at a time when there is paralysis of all motion and sensation no differentiation between complete anatomic section and complete physiologic interruption is possible, in some cases there is later a return of motion, sensation, and other functions. These functions begin to return at variable periods after injury, at times quite late. This observation is not in accord with the dictum that unless some function is found in the first 48 hours no useful function will return. It has been found impossible, from a study of posture and reflex activities to differentiate anatomic section from physiologic interruption. It is necessary to await some recovery of motion or sensation, and therefore those only who show such a recovery have partial lesions. When we, as well as others, have attempted to use posture and reflex activities as an index of completion of a lesion, many errors have been made.

Of 378 patients, some recovery was found in 93, or 24.6%; of sensory function in 89, or 21%, and of motion in 87, or 20%. Of the 87 patients recovering motion, 23, or 26.4%, had slight recovery; 39, or 44.8%, moderate recovery, and 28.8%, marked recovery. Of the 89 patients with sensory recovery, 18% had slight recovery; 45%, moderate recovery, and 37%, marked recovery. With lesions of the cervical portion of the spinal cord, there was a greater percentage of marked recoveries of sensory function than at other levels—51% of the cervical lesions, 16% of the thoracic lesions, 21% of the lumbar lesions, and 33% of the lesions of the conus and cauda. One therefore should be more cautious in respect to rhizotomy in the case of lesions of the cervical region.

The earlier the return of function, the better will be the recovery; thus, with respect to sensation, the median time for the first return of sensation for the whole group was three months, the range being from one week to a number of years. Patients whose recovery was slight showed their first return at a median period of six months; those with moderate recovery, at a median period of four months, and those with marked recovery, at a median period of two months. Sixty-one per cent of the patients with marked recovery, 33% of the patients with moderate recovery, and 31% of the patients with slight recovery showed beginning return in two months or less. However, marked recovery resulted even if the first return was as late as one year.

In regard to motion, 22% of patients with final slight recovery, 47% of those with moderate recovery, and 79% of those with marked recovery had their first return of motion at two months or less, although marked motor recovery occurred when the first return was as long as five months after injury. This indicates that even if recovery of motion or sensation does not occur within a few days, unless the lesion is proved to be a complete anatomic section, recovery may still begin some months after. As an indication of what was considered marked motor recovery, we may mention ability to walk without braces or crutches, or without crutches, or with the aid of braces or cane only, or full recovery of one extremity, or of motion in the thighs and legs, but not of the feet, and, finally, ability to walk without cane, crutch, or braces.

It is of interest to note here that in 36, or 37% of the 93 patients, psychic erection was possible and emissions occurred in 17, or 17%. A sensation of orgasm was present in 14, or 14%. This recovery was unrelated to recovery of bladder and bowel function, at times occurring with the latter, at times independently.

PHYSICAL MEDICINE AND REHABILITATION

A program for physical medicine and rehabilitation is one of the most important parts of the management of the residuals of injuries to the spinal cord and cauda equina.

It contributes to the general well-being of the patient at a time when treatment may be limited to bed activities, and it becomes progressively useful as time and achievement develop. It has been found to be beneficial in increasing appetite, weight, and general strength; in improving circulation, probably in preventing the further development of bedsores, both because dexterity of movement in avoiding injury is developed and a good state of health is promoted. Likewise, it is held valuable in preventing formation of calculi, in diminishing genitourinary infection and in improving bowel action. Nothing contributes more to the morale of the patient, and, as will be seen, the independence brought about by dexterity of movement is the most important factor in the approximation to normal activities.

With the purpose of bringing out certain general principles, 549 patients with lesions of the spinal cord and cauda equina were treated in the physical medicine and rehabilitation service, and the results were analyzed. The patients were divided into two main groups, those with lesions of the cervical portion of the spinal cord, exhibiting paralysis of the lower extremities, as well as of various parts of the upper extremities, and those with lesions below this level—the thoracic and lumbar regions, and the conus and cauda, with paralysis only of the lower extremities and various levels of the trunk. Of the former there were 96 patients, and of the latter, 453. The latter consisted of 327 patients with lesions of the thoracic segments, 106 with lesions of the lumbar portion of the spinal cord, and 20 with lesions of the cauda equina.

In evaluating achievement, a rearrangement of the Veterans Administration's form 10-2555, "My Own Score," served as an index of correction of dysfunction of such activities as were brought about by the injury.

A point system was devised categorically, certain values being assigned to different activities, first for lesions of the cervical region and then for lesions below that level. It is obvious that in case of the latter no credit should be given to certain activities, such as eating and shaving, when the lesion is in the dorsal portion of the spinal cord, and it is equally obvious that it is harder for a patient with a lesion of the cervical portion of the spinal cord to achieve practically all such activities as putting on clothes, propelling a wheel chair, and ambulation, and endurance activities.

What of patients with lesions of the cervical portion of the spinal cord? To the activities collected as Group 1, described as bed activities, with or without the assistance of such devices as splints, cuffs, enlarged grips and holding devices, and counterbalances, a score of 10 points was given when the item was fulfilled. These achievements, which included shaving, eating, and washing, can be performed even though the patient is confined to bed. Logically, those with injuries below the spinal cord were given no credit for such activity.

The activities of the next group in order of progression were those of hand and wheel chair activities, and for their accomplishment 20 points was allotted. The third group consisted of activities related to ambulation on the level ground and erect position activities, and 30 points was allocated to them. The last group, described as "ambulation with elevations and endurance activities," constituted an additional 40 points, making a total of 100 points.

In the case of injuries below the cervical portion of the spinal cord, patients who were trained in the activities in Group 2 were given 15 points; those who could perform Group 3 activities were allotted 25 points, and those who achieved performance in Group 4 activities were awarded 35 points, making a total of 75 points.

The difference in the total points allotted to these two groups was due both to the unallowed credit for activities in the upper extremities in the patients with injury below the cervical region and to the weighting somewhat higher of all the activities of patients with cervical injury, since it is more difficult for patients with paralysis of parts of the upper extremities to perform any activity.

Because of the frequent assumption of the futility of any attempt at restoration of function, or substitution therefor, in the upper extremities when the cervical portion of the cord is injured, the statistics of achievement in cases of lesions at this level are of interest.

Of 96 patients with such lesions, 19, or 19.7%, performed all required possible activities; 24, or 25%, all activities of Groups 1, 2, and 3; 29, or 30.2%, activities of Groups 1 and 2, and 17, or 17.7%, activities of Group 1. In 7, or 7.2%, no rehabilitation was effected. It should be recalled that Group 1 consisted of hand activities, and that Group 2 required eight activities limited to the upper extremities and 16 to the trunk, as well as the upper and lower extremities. Moreover, for the completion of activities of Groups 3 and 4, the upper extremities play a large part in the successful use of braces. These results indicate that the outlook for these patients is not as discouraging as it would seem on casual consideration, and that, as in anterior poliomyelitis, reeducation is successful and substitution of useful function possible.

Does the level of the lesion play any part in the final achievement? In comparing the percentages of patients with lesions at various levels who achieved full activity, (that is, 100 points for cervical lesions and 75 points for lesions at other levels), one finds that 19% of patients with cervical lesions, 32% with thoracic lesions, 62% with lumbar lesions and 70% with caudal lesions accomplished full achievement. Complete achievement was greater as the level descended.

The time required for this accomplishment was an average of 9 mo. for cervical lesions, 7.2 mo. for thoracic lesions, 6.2 mo. for lumbar lesions, and 4.5 mo. for lesions of the cauda equina. The lower the level, the shorter the time necessary for complete rehabilitation.

Is rehabilitation effected with greater ease when the lesion is incomplete? By computing the average of the total points for patients with lesions at various levels and comparing the average for complete lesions with that for incomplete lesions, the following figures are obtained:

Of 96 lesions of the cervical region of the spinal cord, the average for 18 complete lesions was 0.7 point, and the average for 78 incomplete lesions was 54 points. Of 327 lesions of the thoracic portion, the average for 194 complete lesions was 52 points, and that for 71 incomplete lesions was 133 points. Of 106 lesions of the lumbar portion of the spinal cord, the average for 38 complete lesions was 47 points, and that for 78 incomplete lesions was 82 points. Of 20 lesions of the cauda equina, the average was 73 points for three complete lesions and 74 points for 17 incomplete lesions.

Greater degrees of rehabilitation are possible when the lesion is incomplete. In the case of pure lesions of the cauda equina the number is too small to be statistically significant. The chief complications regarding full accomplishment of rehabilitation are decubitus and other ulcers, spasms, contractures, and genitourinary complications.

Fourteen patients, or 14.5%, with cervical injuries; 61, or 20%, with thoracic injuries; 27, or 27.3%, with lumbar injuries, and 2, or 10%, with lesions of the cauda equina, a total of 104, or 18.8%, had decubitus or other ulcers.

With lesions of the cervical region, the average time required to obtain 100 points was 36 mo. when ulcers were present and nine months when they were not. For 60 points, the average was 17 mo. for patients with ulcers and eight months for those without; for 30 points, the average was 12 mo. for patients with ulcers and 4.2 mo. for those without; for 10 points, the average was 31 mo. for patients with ulcers and 3.7 mo. for those without. With thoracic lesions of the cord, the time required to achieve 75 points was 2.2 mo. for patients with ulcers and 7.2 mo. for those without; to achieve 40 points, 19 mo. for patients with ulcers and nine months for those without; to achieve 15 points, 14 mo. for patients with ulcers and 3.6 mo. for those without. With lesions of the lumbar segments, the time required to achieve 75 points was 19 mo. for patients with ulcers and seven months for those without; to achieve 40 points, 16 mo. for patients with ulcers and five months for those without; to achieve 15 points, 12 mo. for patients with ulcers and 2.5 mo. for those without.

Spasms delayed rehabilitation to about the same degree in nine patients with cervical lesions, 33 patients with thoracic lesions, and 15 patients with lumbar lesions, a total of 57 patients, or 10.3%.

Contractures also delayed rehabilitation to about the same degree in 15 patients with cervical lesions, 18 patients with thoracic lesions, and 11 patients with lumbar lesions, a total of 44 patients, or 8.2%. The distribution of genitourinary complications was as follows: 15 patients with cervical lesions, 11 patients with thoracic lesions, and 6 patients with lumbar lesions, a total of 32 patients, or 5.8%. In the group of 549 patients, 222 lesions were produced by gunshot wounds, and 257 by fracture dislocations, and 70 were due to causes not related to injury. No statistically significant difference in ease or degree of rehabilitation was effected among the three groups.

A comparison was made of the rehabilitation effected when the patient had been injured under battle conditions and subjected to treatment limited by the conditions of war, and the rehabilitation effected when the patient had been injured under conditions comparable to civilian life and had then found his way to this hospital. It was found that the civilian type of patient attained effective levels of rehabilitation in a shorter time than the patient injured in battle. It may be possible that the civilian patients were not subjected to complicated wounds and that they received definitive treatment earlier. It is also true that the time after injury plays an important role in final achievement.

A rehabilitation program was started with 207 patients six months or less after injury. Injuries occurred under conditions of civilian life in 154 of those patients, and in battle, in 53. It was consistently found that the earlier the veteran was started on a physical-medicine and rehabilitation program, the better were the results and the less the time required to achieve them. Therefore, the most important difference between battle and civilian conditions is the lapse of time between injury and institution of a physical-medicine and rehabilitation program.

It is of interest to conclude with some figures beyond those concerned only with the achieving of successful movement. Of 78 patients who have been discharged, 22 are in college; 28 are in trade schools; 24 are self-employed, and 4 are employed by others. In the hospital, 10 additional patients received college credit; 22 received high-school diplomas, and 39 were engaged in various avocations.

STATE OF GENERAL HEALTH

In earlier reports, attention has been called to widespread hypoproteinemia, reversal of the albumin-globulin ratio, severe secondary anemia, and amyloidosis.

The occurrence of such states of ill-health varies in respect to time and to where and how the patients are treated. In April, 1946, when we assumed responsibility for the care of these patients, there was a significant number of abnormal albumin-globulin ratios; there were no significantly low amounts of total protein or hemoglobin or of low red blood cell counts. Only 11% of the patients had a red blood cell count of less than 4,100,000, and less than 3% had hemoglobin of under 12 gm. per 100 cc. In about 24% the total protein was less than 6.55 gm. In April, 1946, 46.6% showed an albumin-globulin ratio below 1.5, and 12.4%, a reversal. In April, 1946, only 1% had a ratio above 3.0, and this rose to 30% by July, 1946, the number thereafter diminishing and disappearing. In some instances the diminution of globulin was astounding, in some falling as low as 0.4 gm. per 100 cc. The percentage of albumin-globulin ratios below 1.5 diminished as the months elapsed. In 1949, in most instances the albumin-globulin ratio had assumed a normal value.

In 1948, in 1,172 determinations on 150 patients, significantly low levels of total protein occurred in only 4% of the 150 patients. In only 14 patients was there evidence of a mild hypochromic microcytic anemia.

Some indication of the general state of health may be derived from noting the loss of weight, which is constantly found in these cases. A group of 86 patients were studied with respect to the loss of weight, the time at which the peak of loss of weight was reached, and the amount of weight recovered.

The loss of weight ranged from 10 to 120 pounds (4.5 to 54.4 kg.). The mean loss of weight was 55.6 pounds (27.8 kg.). Twenty-five per cent lost 70 pounds (31.8 kg.) or more. The time when the peak of loss of weight occurred ranged from one month to one year, except for four patients, who continued to lose weight.

The mean time was five months. In one case there was a loss of 70 pounds (31.8 kg.) in the first five weeks.

Treatment devised to improve the physical well-being of the patients resulted in some of the lost weight being regained. The range of weight regained was from 0 to 90 pounds (0 to 40.8 kg.), with a mean gain of 28.71 pounds (14.4 kg.). Five patients regained no weight but did not continue to lose, and four continued to lose weight; four gained more weight than they had lost. The terminal loss of weight ranged from 0 to 80 pounds (0 to 36.3 kg.), with a mean of 31.56 pounds (15.8 kg.). There was no correlation between level of the lesion or injuries of war and peace and the loss of weight.

In a small number of patients ultimately having significant recovery of motion and sensation, the initial loss of weight was less than in the other patients. The lessened indications for transfusions noted elsewhere as years elapse also emphasizes the poor state of health seen originally. Thus, in 1946 there were 569 transfusions of blood and plasma, and in 1949, 249 transfusions.

Attention should be called to the state of ill-being produced by dysregulation of metabolic disturbances and changes in autonomic reflex function when the injury occurs in the cervical and upper dorsal segments. In such cases, diabetes insipidus occurs. Temperature regulation is disturbed, and pyrexia results in hot weather. Because of uncompensated orthostatic hypotension numerous instances of loss of consciousness are noted on changes from the horizontal to the vertical position. At times, abdominal binders are of assistance, and in most instances some autonomic control returns, and the incidence of unconscious states diminishes. Reflex hypertension from distended bladder or rectum and from enemas results, and headache, faintness, and dizziness are often reported. There is evidence that sugar metabolism is disturbed, and it is probable that disturbance of other metabolic functions will be found. There was no disturbance in hunger, appetite, thirst, satiation, or thirst or hunger as the direct result of the injury at any level. A study of the cause of death likewise gives an indication of the resulting lesion. There were 17 deaths among 767 patients admitted, or 2.2%.

Of the 17 patients who died, autopsy was performed on 11, and detailed postmortem reports are available. The causes of death of the 17 patients as listed on the death certificates were as follows, in order of frequency: pyelonephritis, 11 patients; uremic poisoning, 10; bronchopneumonia, 4; hemorrhagic cystitis, 2; ulcerative colitis, 2; pyonephrosis, 1; meningitis, 1; hepatorenal syndrome with vascular collapse, 1; coronary occlusion, 1, and rheumatic heart disease with mitral stenosis and mural thrombi, 1. In the 11 patients on whom autopsy was performed, gross pathologic findings were recorded and are listed in order of frequency of the organs involved (in addition to the primary lesion of the cord): in the lungs, 11 patients; in the liver, 10 patients; in the kidneys, 8 patients; in the bladder, 8 patients; in the skin (decubitus ulcers), 7 patients; in the prostate, 5 patients; in the heart, 5 patients; in the bones (osteomyelitis), 5 patients; in the stomach (gastritis, ulcers), 3 patients; in the testes, 3 patients; in the large intestine, 2 patients; in the small intestine, 1 patient, and in the esophagus (varices), 1 patient.

It is interesting to note that amyloidosis was found in three patients with traumatic paraplegia. In all three patients both the liver and the spleen were involved, and in one the testes also showed amyloidosis, with complete absence of spermatocytes.

The cause of death is usually attributed to infection, especially of the urinary tract, and terminally of the lungs. In practically all cases of injury to the spinal cord, infection of the genitourinary tract exists in a mild or severe degree. This occurs despite the routine use of antibiotics and the careful nursing care and supervision of the genitourinary complications. Why should a few of these patients, all of whom have infection of the genitourinary tract, die? Is it true that their death is due directly to such an infection of the urinary tract, or are there other causative factors in the evolution of their disorder, and complicating diseases, which lead to the terminal state of uremia?

In some cases the successive events in the evolution of disorders is clearly related for the most part to the genitourinary tract. For example, the following successive episodes occurred in different cases: nephrectomy, pyelonephritis, uremia, death; or, cystitis, pyelitis, periurethral abscess, urethral fistulas, nephritis, secondary anemia, anasarca, pleural effusion, uremia, death; or, nephrectomy, nephrolithiasis, perirenal hemorrhage, bronchopneumonia, uremia, death; or, nephrolithiasis, pyelonephritis, urinary suppression, anasarca and ascites, uremia, death.

In other cases, disasters occurred in other parts and led to death, the immediate cause of which was the failure of the kidney because of previous episodes. This may be illustrated by such successions of events in different patients as hemopneumothorax, abscess of the lung, nephrolithiasis, perirenal abscess, anasarca and ascites, death; or, pathologic fracture, rhizotomy, sprue, hypoproteinemia, ileocolitis, nephritis, death; or, hypoproteinemia, repeated genitourinary infections, nitrogen retention, hepatorenal syndrome, vascular collapse, death; or, irreversible secondary anemia, pleural effusion, nephritis, uremia, death.

In some cases, the death was not related to the genitourinary tract, as in the following: Onset of recurrence of rheumatic heart disease, jaundice, auricular fibrillation, congestive failure, death; or, chordotomies, osteomyelitis, chronic pancreatitis, death.

An analysis of the clinical histories of the patients who died shows that in most instances they were subject to more than infection of the genitourinary tract. Many of them had had recurrent attacks of sepsis. Most of them had undergone several surgical procedures. Severe decubitus ulcers, osteomyelitis, heart lesions, pulmonary disease, gastrointestinal complications, and general nutritional disturbances were encountered. It may be seen from the aforementioned cases that when the terminal picture was that of uremia due to renal failure other factors often contributed to such an outcome.

The importance of this approach to the problem of the "cause of death" lies in the calling of attention to appropriate measures in planning the best program of care for paraplegic patients. In addition to the use of antibiotics and to careful routine and repeated studies of the genitourinary tract, attention is called to the general bodily status of the patient, his nutritional state, his reactions to surgical procedures, and his organs of defense concerned with antibody and resistance elements, such as the spleen and reticuloendothelial system.

ADMINISTRATION

The Center at the Veterans Administration Hospital, Hines, Ill., having a total bed capacity of 300, was first opened April, 1, 1946. It occupies 12 wards of 25 beds each. Most of the patients are placed in large wards. There are a number of private rooms; these are reserved for patients who are critically ill. It has been found that patients do much better in large wards than in private rooms.

The early problems in the treatment of spinal-cord injuries as a result of war injuries were different than those concerned with spinal-cord injuries as a result of civilian injuries. The patients with war injuries came to us with acute conditions, such as anemia, hypoproteinemia, bladder infections, calculi, tidal drainage, decubitus ulcers, malnutrition, and amyloidosis. These problems required a large nursing and attendant staff. As the result of improved and continued treatment of bedsores, bladder and bowel control and general health, the numbers necessary diminished. In April, 1946 there were 118 nurses and 179 attendants; in March, 1947, 106 nurses and 140 attendants; in December, 1947, 78 nurses and 130 attendants; in April, 1948, 92 nurses and 120 attendants; in December, 1948, 58 nurses and 114 attendants; in July, 1949, 50 nurses and 106 attendants, and in January, 1950, 44 nurses and 96 attendants.

By the end of 1949, only 34% of the patients had sustained injury as the result of war, 66% being in the hospital for civilian injuries. The civilian patients had fewer complications than patients with spinal-cord injuries resulting from war wounds, thus requiring less personnel; this also contributed to the decreased need for as large a nursing and attendant personnel. Another indication for the need of a smaller personnel now than in 1946 may be found in comparing the numbers of transfusions given patients with spinal-cord injuries for medical conditions, such as anemias and hypoproteinemia, but not for surgical conditions, in 1946 with those at the present time. In 1946, after April, there were 569 transfusions; in 1947, 516; in 1948, 297, and in 1949, 244.

Disciplinary Boards.—After the change from Army to Veterans-Administration control, a feeling of almost arrogant independence developed in the patients, who felt that they were protected by public clamor and political favor, combined with the fact that they were free from Army discipline and punishment under the Articles of War. In addition, a firm Veterans Administration policy for violations had not been developed, in spite of the efforts of the Manager to enforce the regulations. As a result, disciplinary problems began to increase and were present almost daily. The greatest problem at that time was alcoholism, and, to a less extent, gambling. Not infrequently, the patients became openly abusive of members of the ward personnel, and occasionally there were altercations among the patients themselves. Gradually the situation began to improve with regard to alcoholism as a result of constant enforcement of all violations by the restriction of passes for varying lengths of time—from one to three months. Alcoholism is still present among a few chronic offenders and crops up occasionally in cases of readmission of old patients. There is a more or less general use of alcoholic beverages on the part of almost all patients while on pass or leave from the hospital, more for social reasons than because of addiction.

Although this problem is still present, violations are infrequent and are confined largely to the winter months, when driving is hazardous and the patients are unable to move about freely, outdoors, in their wheel chairs.

Car Driving.—When automobiles for service-connected patients were authorized, a training program was instituted to teach the patients to drive; and when they became proficient, they were permitted to drive their own cars and were licensed by the state. There were a number of instances of patients who, without permission of the Veterans-Administration driving school, acquired licenses by going to nearby towns. At first there were a number of automobile accidents, in excess of those in the general public, but at this time the situation has improved to the point where there are very few. The proficiency and ability of individual drivers have improved greatly with the lapse of time.

Games.—Games in which patients with spinal-cord injuries can injure themselves are not permitted. For example, basketball games are a dangerous sport in that a patient may sustain a fracture or acquire a decubitus ulcer as a result of friction. Our patients were prohibited on medical grounds from participating in the championship basketball games that were touring the country last year. They have the facilities of a large gymnasium, where they can practice archery, bowling, and other harmless sports.

122 S. Michigan Ave.

ABSTRACT OF DISCUSSION

Dr. L. W. Freeman, Indianapolis: Only a few years ago, opinion was strongly entrenched to the effect that few paraplegics could be expected to survive the many complications facing them, and those who did could look forward to little more than a parasitic life. The second world war altered that concept, when the Surgeon General began to make special provisions for their care. Thus, men like Bors and Kuhn were able to evolve centers for special care. Some of these were remodeled and expanded before being turned over to the Veterans Administration. That these centers have been maintained, and even improved, as is indicated by the present paper, is a tribute to the insight and ability of Hawley and Magnuson. The most important factors in the success of this type of case handling have been the segregation of the patients, the establishment of the wards at a department level, and the integration of specialty services. To illustrate Dr. Pollock's reticence in recording his actual achievements, buried in the statistics presented, I should like to point out that it was some of his own patients who initiated the drive to make the excellent care they received available to the civilian paraplegic. It was to this end that they, the veteran paraplegics, formed and incorporated in the State of Illinois the National Paraplegia Foundation, on whose medical advisory committee I have the privilege of serving. Dr. Pollock has emphasized the need for a cautious approach to the various complications. One must not, however, fall into the fallacious idea that operative techniques are radical, for often they are the only method of conserving life. Functional regeneration after transection of the spinal cord has been observed in the rat, the cat, and the dog. In our laboratories, we have transplanted spinal nerve roots, with functional return, in the dog and the primate. The possibilities of application of such techniques are presently under study. [Slide.] I show a gross anatomic picture of a plasma-clot suture of spinal nerve roots in a primate. Stimulation of the proximal end gave a peripheral muscular response, and the microscopic sections showed a liberal downgrowth of fibers to the muscle. It should be pointed out that the roentgenographic demonstration of laminar fractures and intervertebral disk protrusions is unreliable, making early and careful laminectomy the most conservative therapy possible in regard to the preservation of spinal-cord structure. Moreover, many poorly functioning neurogenic bladders are amenable to selective neurosurgical procedures.

IMPROVED TECHNIC FOR DIAGNOSING RINGWORM INFECTIONS AND MONILIASIS

A. M. Kligman, M.D., D. M. Pillsbury, M.D.,
and
H. Mescon, M.D., Philadelphia

Although superficial fungus infection of the skin is a common disease, it has been our experience that diagnosis of the condition is often made on the basis of inadequate evidence. Ringworm, especially of the feet, is a popular diagnosis among both physicians and laymen. The diagnosis is usually based on brief clinical inspection without resort to confirmatory laboratory procedures.

A false diagnosis of ringworm carries the hazard of exposing the patient to therapeutic attacks that at best may not be helpful, and at worst may be damaging. We have repeatedly had the opportunity to observe patients with various types of contact dermatitis who have received the wrong treatment, often with great harm to themselves, because of a clinical misdiagnosis of ringworm. On the other hand, the failure to make an accurate diagnosis, particularly in the more resistant cases such as ringworm of the nails, entirely precludes rational therapy.

Confirmation of a diagnosis of ringworm is afforded by two laboratory procedures: (1) culture of the organism; (2) microscopic demonstration of the fungus in tissue. Although isolation of the organism in culture is often helpful in prognosis, this procedure can scarcely be recommended to the busy general practitioner. Moreover, even when good laboratory facilities are available, attempts to isolate the organism are successful in only 40 to 60% of the microscopically proved cases of ringworm. Therefore, microscopic examination of skin scrapings is a more feasible and valuable diagnostic technique. The simplicity of this examination also recommends it.

The fungi causing superficial skin disease grow in the horny outermost stratum of the epidermis. They appear in this dead substratum in the form of branching threads or filaments (hyphae). They are considerably larger than bacteria. The organism that causes moniliasis (Candida albicans) shows yeastlike forms (budding cells) as well as hyphae. The microscopic detection of a filament or even a small fragment of a filament in a skin scraping is sufficient to establish a diagnosis of superficial fungus infection.

Up to the present time the potassium hydroxide preparation has been the accepted procedure for demonstrating fungi in the skin. This technique requires that the skin scrapings be mounted in a drop or two of 10% potassium hydroxide on a slide. Although the hydroxide solution serves to clear the tissue and thus increases the visual contrast of the fungus, the value of this method is nonetheless limited because the preparation is colorless. The differentiation of artifacts such as the "mosaic" fungus (not a fungus at all) is often difficult. Moreover, fungus elements are exasperatingly scarce in some specimens, and 15 to 20 minutes of close scrutiny by a skilled observer may be required to detect the organism in an unstained preparation.

In previous communications, the Hotchkiss-McManus stain has been recommended as a superior method of demonstrating fungi in tissue.[1] The two fundamental steps in this procedure are treatment of the skin scrapings on a slide with 1% periodic acid [2] followed by exposure to the Schiff reagent (decolorized basic fuchsin). The necessity of using the Schiff reagent limits the value of this technique for routine work because of the relative instability of the solution. Schiff reagent is not readily prepared and usually has to stand overnight before use. Arzac [3] has succeeded in modifying the Hotchkiss-McManus stain so that ordinary basic fuchsin solution is used instead of the Schiff reagent. This is advantageous because basic fuchsin solution is stable. Both the Hotchkiss-McManus technique and Arzac's modification are general stains for various substances belonging to the class of complex polysaccharides. These stains are in no sense specific for fungi. Our interests, however, have been confined to the adaptation of these procedures to the specific purpose of demonstrating fungi. In particular, the aim of the present study has been to develop a modification so simple as to make this procedure an available diagnostic tool for routine use. The method to be described may be readily employed in clinic and private practice wherever routine diagnostic laboratory procedures are being performed. Specifically, it has been

found very useful in the diagnosis of dermatophytosis of the feet, tinea corporis, tinea capitis, onychomycosis (ringworm of the nails), tinea versicolor and moniliasis.

METHOD

The method of collection of material is most important. Preferably, a drop or two of Mayer's glycerol albumin (purchasable from any supply house) is placed directly over the lesion. The lesion is then vigorously scraped with a blunt knife. The albumin causes the scrapings to stick to the knife, and also accomplishes the removal of the horny material in the form of macerated, thin shavings. It is essential that thick pieces be avoided. The macerated material on the knife is then transferred to a slide and rubbed over the surface so as to effect an even distribution. The albumin also enables adherence of the material to the slide during the staining procedure. Slides prepared in this way can be shipped by mail and stained without loss of brilliance weeks later, if necessary. Scrapings from nails may be collected in the same manner, although more vigorous scraping is required. Whenever possible in cases of onychomycosis, horny material under the nail should be collected. The likelihood of a positive result in onychomycosis is greatly improved by the collection of a copious amount of material since fungus elements may be very scarce.

Comparison of the Potassium Hydroxide Method with the Basic Fuchsin Staining Technique in Suspected Cases of Superficial Fungus Infections

Condition	No. of Patients Examined (in Suspected Cases)	No. of Positive Diagnoses from Stained Preparations	No. of Positive Diagnoses from KOH Preparations	No. of Positive Diagnoses from KOH Preparation but not in the Stained Specimens	No. of Positive Diagnoses from Stained Preparations but not from the Potassium Hydroxide Specimens
Ringworm of the glabrous skin and the feet	164	47	39	0	8
Fungus infection of the nail	22	13	9	1	5

On the other hand if the laboratory receives the material in the form of thick pieces of nail or the tops of vesicles, it is necessary to scrape these specimens with a sharp knife so as to procure a thin smear. In the latter case the slide should be prepared beforehand by smearing a drop of Mayer's glycerin-albumin over it. The thin scrapings are then rubbed over the slide as before.

In suspected cases of moniliasis of the mouth or vagina, the swab used to collect the sample is simply rubbed over an albuminized slide. The following procedures are best carried out in a series of Coplin staining jars that may be permanently set up for routine use:

1. Immerse the slide for one minute in 95% alcohol, immerse it for five minutes in a 5% aqueous solution of periodic acid.
2. Transfer it to the following solution for two minutes:

Basic fuchsin	0.1 gm.
95% ethyl alcohol	5 cc.
Water	95 cc.

(Dissolve the basic fuchsin in the alcohol and then add the water.)

3. Rinse briefly in tap water.
4. Immerse in the following solution for 10 min.:

Zinc hydrosulfite	1.0 gm.[4]
Tartaric acid	0.5 gm.
Tap water	100.0 ml.

This solution is stable for at least one month if it is kept in a closed jar, and can be used over and over again. It may be conveniently kept in a stoppered bottle and poured into a Coplin jar just before use, or a screw-cap type of Coplin jar may be used. Zinc hydrosulfite is a white powder and a fresh solution can be prepared in a few minutes. The freshly prepared solution contains finely dispersed sulfur which, however, does not interfere with immediate use. Within 24 hours the sulfur will have settled to the bottom, leaving a clear solution. Removal of the sulfur by filtration is not required. The solution is usable as long as it continues to have a strong smell of sulfur dioxide.

5. Rinse the slide briefly in water.
6. Dehydrate and mount. Immerse in 95% alcohol, absolute alcohol, xylene, and a final xylene solution, for one minute, in each, and mount in balsam or HSR[5] mounting medium. Preparations prepared in this fashion are permanent and may be filed. If semipermanent preparations are satisfactory, the specimen may be mounted in a drop or two of polyvinyl alcohol mounting medium immediately after step 6. This eliminates the necessity of dehydrating and clearing; however, the color of specimens mounted in polyvinyl alcohol begins to fade after a few days. The polyvinyl alcohol mounting medium can be prepared according to the directions given by Huber and Caplin.[6] If the specimen is to be examined the day of preparation or on the next day it may be mounted in ordinary glycerin directly after step 6. This is the simplest procedure if, as is usual, the slides are to be disposed of shortly after inspection. Mounting in glycerin is recommended for routine use since this eliminates the several steps required to dehydrate and clear the specimen.

RESULTS

The fungi are stained red. The horny tissue is either colorless if fairly thin, or light red if thick. Even in thick smears, however, there is sufficient contrast between the fungi and the keratin to afford ready detection of the fungus.

For the past six months this technique has been in routine use in the dermatology clinic of the Hospital of the University of Pennsylvania. As a basis of comparison, the potassium hydroxide method has been done in parallel on each specimen. The clear-cut superiority of the stained slides is demonstrated by the evidence presented in the Table. The advantage of this method lies not only in permitting a higher percentage of positive diagnoses but also in the brief time required to find the fungus in a positive smear. These advantages offset the time and effort required to stain the preparation. The staining method is, however, a much more complicated one than the potassium hydroxide procedure.

COMMENT

It may be observed that there was only one instance (a case of onychomycosis) in which fungi were demonstrated by the potassium hydroxide method and not in the stained smear. Nonetheless, it is precisely in cases of fungus infection of the nail that the staining method has proved most valuable. Not infrequently, even when abundant material has been collected on several slides, only a single fungus fragment may be present. This fragment is readily missed in an unstained preparation. It should also be pointed out that in scrapings from cases of onychomycosis the fungus elements are often in a degenerated state so that they do not stain as brilliantly as the organisms found in glabrous skin lesions. One may observe from the Table that if the potassium hydroxide method alone had been used in cases of ringworm of the skin and feet, about 17% of the positive cases would have been missed.

The staining method has particular value in the diagnosis of moniliasis. We have been repeatedly surprised by the large quantity of organisms observed on the stained slide when the potassium hydroxide preparation of the same specimen showed a paucity of fungus elements. Brilliant preparations result from material collected in cases of moniliasis of the mucous membranes. The method should be particularly valuable to gynecologists for the detection of monilial vaginitis.

One should be aware that the skin supports as part of its normal flora a group of budding yeastlike fungi. These are mainly the so-called lipophilic fungi belonging to the genus Pityrosporum (including Pityrosporum ovale, the "bottle bacillus," falsely implicated as a cause of dandruff). These normally occurring organisms should not be confused with the organism causing moniliasis (C. albicans). The lipophilic fungi are much smaller, and exhibit only round or oval budding cells, never hyphal threads.

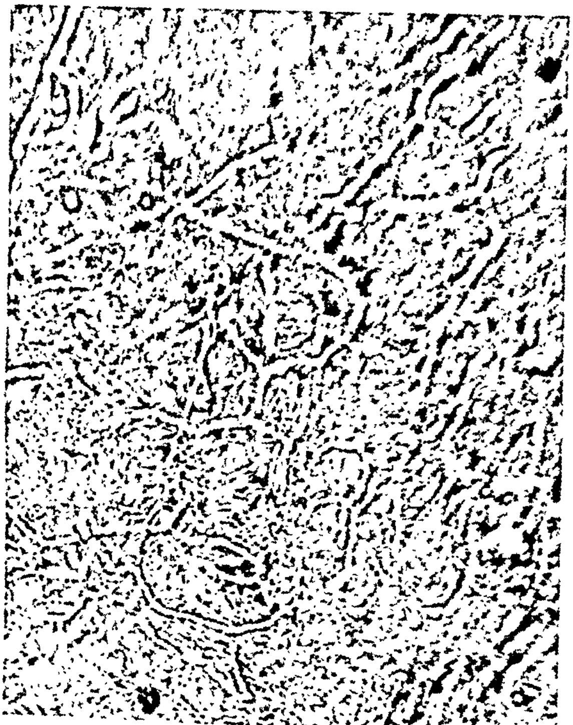

Fig. 1.—Potassium hydroxide mount from a case of ringworm of the skin. The fungus threads are poorly defined.

The fungus in cases of tinea versicolor is brilliantly demonstrated by this staining technique. However, the fungi are ordinarily so abundant in this disease that the simpler potassium hydroxide method is usually satisfactory.

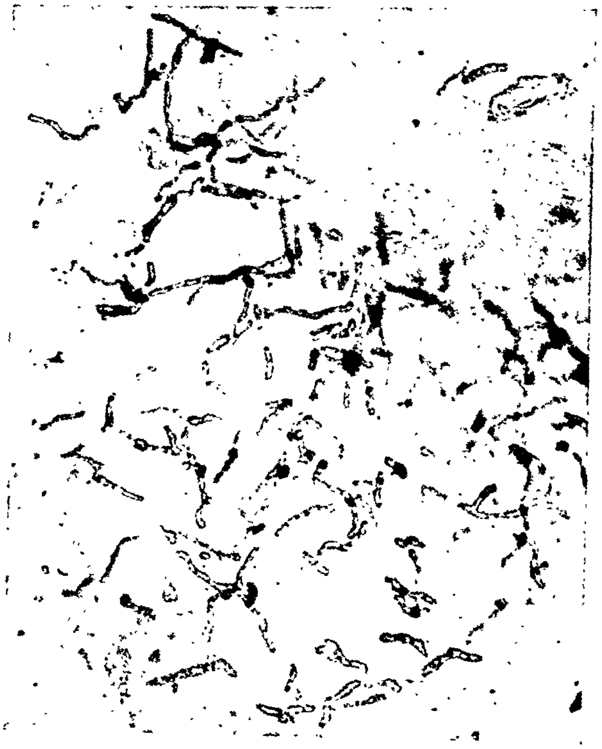

Fig. 2.—Stained mount from the same case. The hyphae are strikingly visible.

Another recently described method of staining fungi in skin scrapings with methylene blue has proved unsatisfactory in our hands.[7]

SUMMARY

1. A method is described of staining fungi in skin scrapings with basic fuchsin.

2. The method is superior to the potassium hydroxide technique, since a correct diagnosis can thus be made with much greater accuracy.

Atom Bomb Injuries.—The prognosis of radiation injury is summarized as follows: (*a*) If vomiting occurs on the day of the bombing and is followed by diarrhea, prostration, continued vomiting, anorexia and fever, survival is improbable, and death will occur in a matter of days. (*b*) If vomiting occurs on the day of the bombing and is followed by an asymptomatic period of one to three weeks before appearance of the typical symptoms of radiation injury (purpura, epilation, ulcerations of the mucous membranes, and gastro-intestinal disturbances), survival is possible. (*c*) If there is no vomiting on the day of the bombing, survival is probable unless there are complicating factors such as burns, thermal injuries, traumatic injuries, or concomitant epidemics. Epidemics in a leukopenic population may be catastrophic.—Comdr. Eugene P. Cronkite, M.C., U.S.N., Radiation Injuries Produced by Atomic Bombs, *Radiology*, May, 1951.

RHEUMATIC NODULES IN TUBERCULOSIS

Antonio Valdés-Dapena, M.D.
and
Marie Valdés-Dapena, M.D., Philadelphia

While studying the hearts of patients who died from tuberculosis, not infrequently we have found cellular infiltrations in the myocardium indistinguishable from Aschoff bodies. In the English literature such lesions apparently have not been described. They are not mentioned in Rich's comprehensive contribution [1] or in any of the texts of pathology. In the United States only Gouley, Bellet, and McMillan (1933)[2] have observed "submiliary foci of epithelioid cells around small blood vessels" and "large and small nodules of endothelial and round cells" which they interpreted as "tuberculous granular infiltration" in six cases of tuberculosis.

As the occurrence of Aschoff bodies in tuberculosis seems to be of greatest importance, not only for the understanding of this disease but especially for that of rheumatic heart disease, we felt it desirable to report our observations and briefly discuss their significance.

MATERIAL

This is a study of the hearts of 63 patients who at autopsy were found to have tuberculous lesions. In 62 of these patients the tuberculous involvement was in the lungs, and in all it was the primary cause of death. In one tuberculosis was found primarily in the adrenals, and that was the primary cause of death.

Types of Tuberculosis in Sixty-Three Cases of Tuberculous Lesions

Type	No. of Cases
Extensive ulcerocaseous pulmonary tuberculosis	28
Same with miliary spread	2
Fibrocaseous pulmonary tuberculosis	17
Same with miliary spread	2
Fibronodular pulmonary tuberculosis	3
Minor pulmonary lesions with acute miliary spread	10
Adrenal tuberculosis	1
	63

On an average, four portions of myocardium were taken, usually one from the septum and the rest from the left and right ventricles. From these between four and 16 microscopic slides were made in each case and stained in the usual routine hematoxylin and eosin method. In none of these hearts was there any sign, grossly, of active rheumatic heart disease. All patients with healed rheumatic lesions or a history of rheumatic fever were excluded from this series.

The accompanying table indicates the types of tuberculosis found in our cases.

GROSS FINDINGS

Most of the hearts were under the average normal weight. The myocardium was usually pale and in many cases exhibited the consistency and color which generally lead to the diagnosis of cloudy swelling. Grossly there was no indication of any specific myocardial change that might correspond to the lesions encountered microscopically. Three hearts showed typical tuberculous pericarditis, and a few showed old pericardial fibrosis or adhesions.

MICROSCOPIC FINDINGS

Miliary tubercles were not found in any of the sections examined. In spite of the fact that many of them had extensive miliary spread and most of them presented miliary tubercles, at least in the spleen and liver, no tubercles have been found in the myocardium. This does not refer to our experience in this series alone.

Nontuberculous granulomatous lesions were found in 13 cases. These granulomas could be classified in three groups:

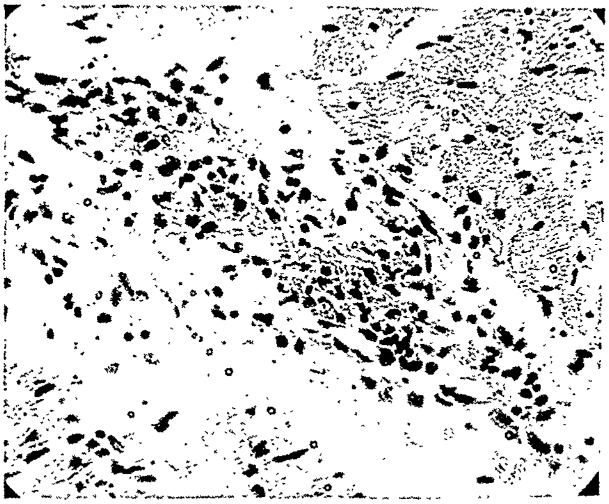

Fig. 1.—Typical young Aschoff bodies.

1. *Aschoff Bodies* (figs. 1 through 4).—Of these there were seven. All conformed to the criteria set for the identification of "rheumatic nodules." They were located in the interstitial spaces and were made up of collections of large spindle-shaped cells with a clear oval nucleus in which the chromatin tended to form a central irregular line oriented in the longitudinal sense (Anitschkow cells) and a sprinkling of "Aschoff cells" with mildly basophilic cytoplasm. The American Heart Association sets down the following pattern for Aschoff bodies [3]: A. Early Aschoff bodies (fig. 1)—Aschoff cells are conspicuous large cells with granular basophilic cytoplasm, prominent nucleus, vesicular nucleoplasm, and dense nuclear membrane; occasional polymorphonuclear leukocytes may be present, and surrounding collagen fibers are swollen and eosinophilic. B. Later Aschoff bodies (fig. 2 through 4)— Cells may become larger and multinucleated, and small lymphocytes and fibroblasts may appear.

[3] Criteria Committee of New York Heart Association: Nomenclature and Criteria for Diagnosis of Diseases of the Heart, New York, New York Tuberculosis and Health Association, 1940.

2. *Aschoff Bodylike Granulomas.*—Of these we had one. They represent perivascular infiltrations which are very suggestive of rheumatic nodules but are not entirely identical with the prescribed picture.

3. *Nondescript Granulomas.*—There were five of these. In this group were included aggregates of cells which constituted definite and striking interstitial lesions but very easily could be segregated from the group of typical Aschoff bodies. They were made up of Anitschkow cells together with plasma cells or of large cells with prominent nuclei and reticular chromatin without Anitschkow cells. Although they were not typical Aschoff bodies, they certainly might be termed such; these, too, might be called rheumatic nodules.

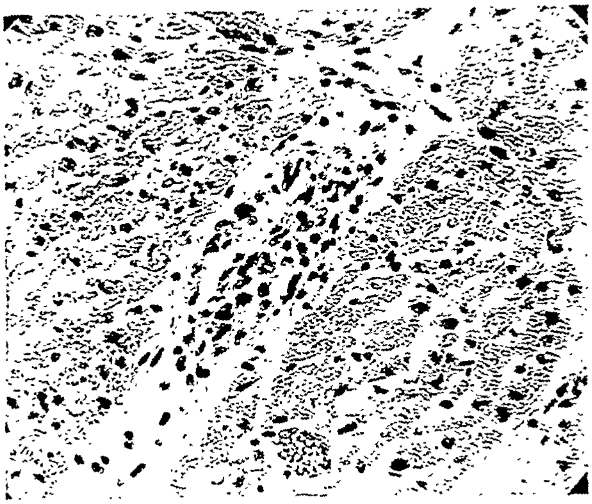

Fig. 2.—Typical adult Aschoff bodies.

4. Finally, diffuse cellular infiltrations, which were not granulomas, were found in four cases. Curiously, the four were quite distinctly different. One showed an intermingling of polymorphonuclear leukocytes and monocytes (fig. 8). In another case there was a fresh infiltration with polymorphonuclear leukocytes (fig. 7). Monocytes and lymphocytes were found in a third case, and the other showed a pure lymphocytic infiltration. These were taken to be a nonspecific change, although the question remains open as to whether they were early stages of a tuberculous lesion or whether they might have been associated in some way with the subsequent formation of granulomas. They were not coincident with the granulomas.

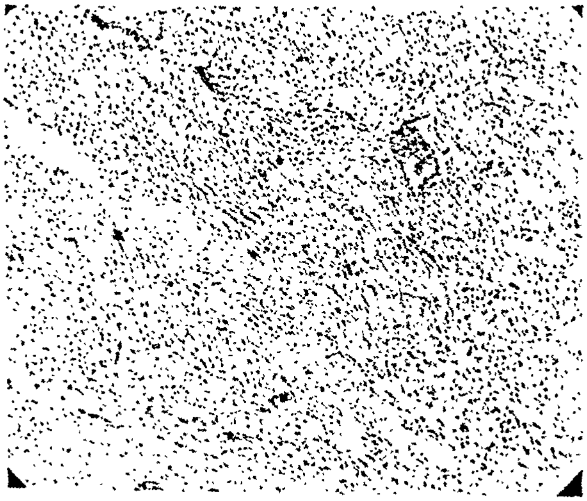

Fig. 3.—Typical adult Aschoff bodies in upper center portion.

COMMENT

In reviewing the literature we found that Aschoff bodies and similar granulomas have been described fairly often not only in tuberculosis but also in other infectious diseases.[4] The interpretations of these offered by the different authors have been different. To date the issue seems far from settled. The specificity of the Aschoff bodies as a manifestation of rheumatic fever in the strictest sense is defended by many[5]; the nonspecificity of this lesion is maintained by others.[6] Finally, some have gone further and consider the Aschoff body, because it may be found in tuberculosis, as the connecting link between the two diseases.[4b]

The first point that must be discussed is whether the lesions we have found are identical with Aschoff's rheumatic nodule. Staunch defenders of the specificity theory have always maintained that similar lesions found in nonrheumatic patients did not look to them like Aschoff bodies. Soon after the latter were described, Lubarsch[4a] reported finding similar or identical structures in patients with scarlet fever. Fahr[5a] came to the defense of the specificity theory by stating that he could see definite differences between the true lesions encountered in rheumatic patients and the spurious ones occurring in scarlet fever. More recently, Stoeber[4e] repeated the observation, maintaining the distinction, and he even went over 18 cases of tuberculosis to answer the claims of those who had found granulomatous lesions in the latter disease. He found there, as he states, "no Aschoff bodies."

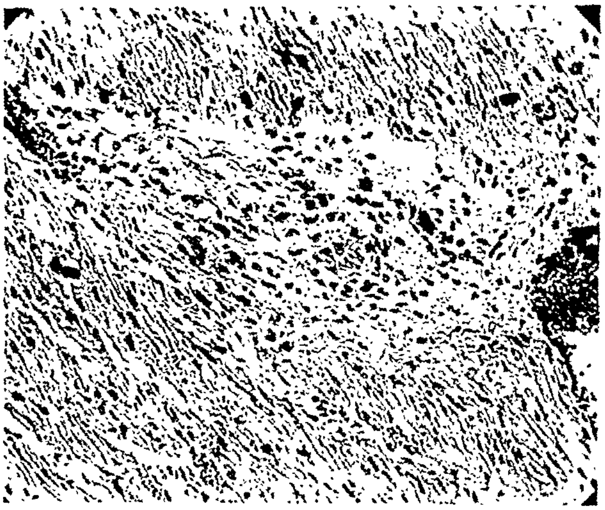

Fig. 4.—Same section as figure 3 under high power.

On the other hand, Masugi and associates[4b] on examining 215 hearts of tuberculous patients found 35 (16.3%) with interstitial cellular collections whose appearance showed all the transitions from typical Aschoff bodies to structures very similar to miliary tubercles. Ozawa [4d] examined 187 hearts of patients dying of pulmonary tuberculosis. In 41 (21.9%) of these he found "granulomata." Yamada,[4c] in 350 hearts of tuberculous patients, found 39 (11.1%) with interstitial lesions, 2 of which were identical with Aschoff bodies, 14 of which were very similar, and 23 of which showed a tendency toward epithelioid tubercle formation. The same author studied 120 cases of various other diseases, including scarlet fever, "croupous pneumonia," glomerulonephritis, and others; 13 of these showed myocardial lesions similar to Aschoff bodies. Patients with carcinoma were free of such lesions.

[6] Klinge, F.: Ergeb. d. allg. Path. u. path. Anat. **27**: 1, 1933.

Brockhausen [7] reported one case in which typical tubercles were found side by side with not only granulomas but also lesions resembling periarteritis nodosa. He described the granulomas as differing from Aschoff bodies in their loose texture and their profuse lymphocytic infiltration.

In our appraisal of the question of the histological specificity of the rheumatic nodule it may be well to bring up the matter of whether every lesion found in the myocardium of unchallengeable cases of rheumatic fever conforms exactly to the criteria of morphology of an ideal Aschoff body. Perhaps the percentage of "perfect" Aschoff bodies in rheumatic hearts with myocardial changes is not much different from that found in nonrheumatic hearts showing granulomatous myocardial lesions, as, for example, in our group. It seems to us very likely that in examining sections from a heart with obvious gross rheumatic lesions, the observer might not be too exacting as to the standards used in labeling any granulomatous lesion found an Aschoff body.

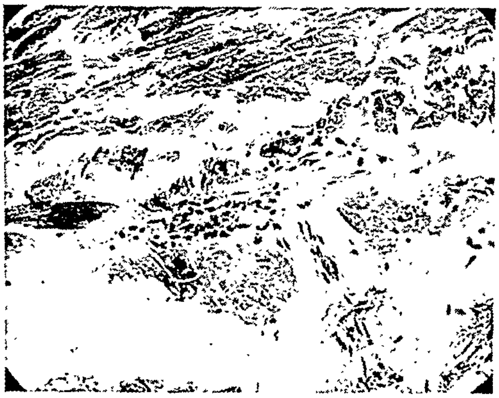

Fig. 5.—Typical small Aschoff bodies.

Since a good many of the lesions found in our cases conformed in every detail to the strictest criteria, we feel that it is permissible to say that typical Aschoff bodies occur in the hearts of some tuberculous patients showing no indication of rheumatic fever, active or latent.

Let us consider now the significance of our observations. As expressed by Masugi [4b] they can be explained in one of three ways: 1. A rheumatic disease of the myocardium existed in these patients coincidentally with tuberculosis and without any other sign of rheumatic fever. 2. Rheumatic fever and tuberculosis are one and the same disease. 3. Aschoff bodies are the expression of a nonspecific tissue response to varied stimuli, probably of an allergic nature.

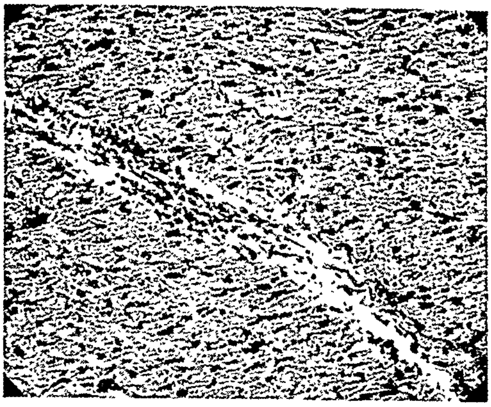

Fig. 6.—Typical small Aschoff bodies.

The first possibility remains theoretically tenable but seems highly improbable because the percentage of positive findings is far higher than would be warranted by the statistical probability of coincidence of the two diseases.

The second view has been held by various authors. Tuberculous rheumatism, as such, was first postulated by Poncet in 1902. Loewenstein's positive blood cultures for tubercle bacilli in cases of chronic and of acute polyarthritis strengthen this view. These observations were never satisfactorily confirmed, and the theory fell into disrepute. Recently, Masugi,[4b] on the histopathological findings, again postulated the relationship between the two diseases. He was impressed particularly by the gradation of myocardial lesions from the typical tubercle to the Aschoff body. With his co-workers he studied 24 rheumatic fever patients, all of them with endocarditis, and found that 11 of them had signs of tuberculosis, five of them with active lesions. Finally, Lewkowicz [8] has described an organism which he calls "tuberculo-coccoid" and designated it as the agent of a group of diseases

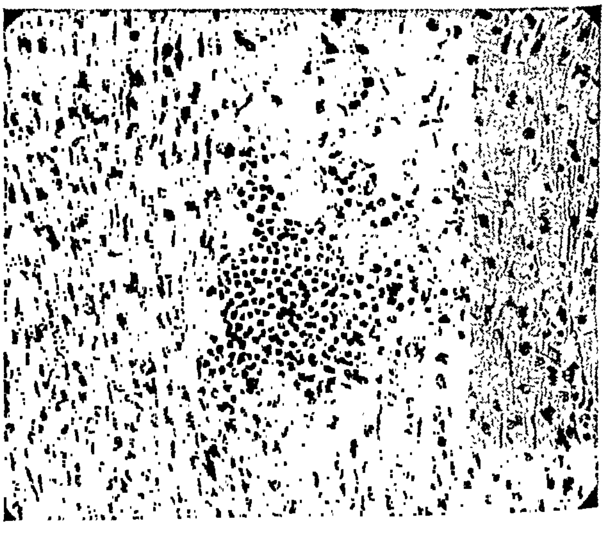

Fig. 7.—Interstitial myocarditis; fresh infiltration with polymorphonuclear leukocytes.

---

7. Brockhausen, K.: Virchows Arch. f. Path. Anat. 274: 302, 1930.
8. Lewkowicz, K: Beitr. z. klin. Tuberk. 92: 680, 1939.

which he has classified as "inflammatory tuberculosis." Among these he would include rheumatic fever. This acid-fast "coccoid" is almost always intracellular, may be small enough to be filterable, and, according to that author, shows transitional stages toward the bacillary form. The same writer refers to the obtaining by Coronini of positive tubercle bacillus cultures from hearts of rheumatic patients.

The search for an etiological agent of rheumatic fever has long been directed toward the acid-fast organisms. It is well known that no convincing evidence has ever been produced in this sense. While the chapter is not closed, at this point it seems highly problematical that rheumatic fever may be a manifestation of tuberculosis.

It remains as the most suggestive hypothesis that the Aschoff body and the morphologically related granulomas may be an allergic response to varied allergens, among which the tubercle bacillus is a prominent one.

There has been experimental evidence to show that interstitial granulomas may be produced in the heart by different antigens. This was first brought into prominence by the work of Klinge,[6] using protein sensitization and reinjection. He observed all types of granulomas up to typical Aschoff bodies. His conclusion was that these lesions were not specific. Later, Rich and his group[1] produced similar lesions almost at will in their experiments dealing with sensitization to foreign proteins. Yamada[4c] sensitized rabbits to the tubercle bacillus and, after a second inoculation, was able to demonstrate in the heart and muscles micronodular lesions closely resembling the Aschoff body. Saphir[9] speaks of granulomatous myocarditis due to hypersensitivity to chemicals (arsenic and others).

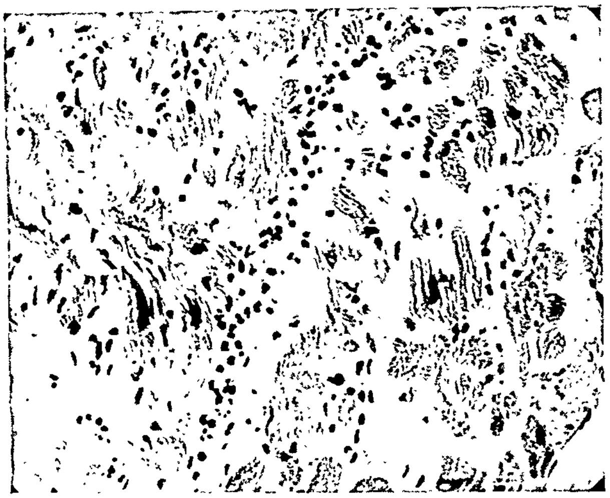

Fig. 8.—Interstitial myocarditis; intermingled polymorphonuclear leukocytes and monocytes.

Allergy admittedly plays an important role in the course of pulmonary tuberculosis. The relationship between the allergic status of the tuberculous patient and the development of interstitial rheumatoid granulomas is not quite clear. In Ozawa's series there was a marked predominance of exudative tuberculosis, widely regarded as a manifestation of increased allergic response. Masugi found no significant distribution but, believing that the granulomas were a form of tuberculosis, came to the conclusion that they represent a type of reaction in which the tissue overcomes the invading organism to the point of destroying it entirely. That explained, in his mind, why bacilli were never found in these lesions.

In our material typical Aschoff bodies occurred largely in cases of exudative tuberculosis. We, therefore, feel that it is logical to associate these lesions with a reaction of the type observed by Klinge and Rich due to hypersensitivity to various allergens, in this instance the tubercle bacillus.

SUMMARY AND CONCLUSIONS

The hearts of 63 tuberculous patients were examined. Thirteen revealed granulomatous lesions in the myocardium. Seven of these lesions were identical with Aschoff bodies. There were no gross anatomical signs of latent, healed, or active rheumatic heart disease in any of these patients. In the light of present knowledge, our observation, or interpretation, of these lesions supports the conclusions of those authors who believe that rheumatic nodules are allergic phenomena due to various allergens rather than the specific response to a specific agent.

Leukemia.—In this dread disease there are numerous manifestations which are recorded as isolated facts in textbooks of medicine without any emphasis on the conclusions which can be drawn from them and without any attempt to bring them into a perspective where they can be used to discuss the nature of the disease. The spectacular and absorbingly interesting hematological changes have received the most minute attention, and this alone has tended to overshadow the morbid anatomy and basic pathology and also to divert attention from certain clinical facts which may provide the clue to the elucidation of the cause and the devising of appropriate treatment. . . . We are thoroughly familiar with two types of the disease which we designate as leukemic or aleukemic, according to the state of the peripheral blood, but these do not differ greatly in clinical features save that in aleukemic cases the lymph nodes, the spleen, and the liver may not be so grossly enlarged at the outset. This fact, that the disease may be leukemic or aleukemic, is accepted as a commonplace, a mere variation in manifestations. It has not given rise to argument and serious discussion. Yet the fact that two types exist suggests the derangement of two different processes which, on rational grounds, should be physiologically interlocked. I refer first to the process of maturation and, secondly, to the process of release into the circulation. . . . In frank leukemia, there appears to be inhibition or retardation of maturation in whole or in part, combined with lack of control over release, since vast numbers of cells, including primitive ones, flood the circulation. In the aleukemic disease lack of maturation is a prominent feature, but the release mechanism is largely intact in that the numerous primitive cells in the marrow may not reach the circulation except in small numbers.

These facts make it abundantly clear that we know little or nothing of the physiology of leucopoiesis, and I am convinced that we shall not understand leukemia until some of these basic physiological facts have been determined. If half the time and energy which have been devoted to devising and exploiting empirical remedies for the symptomatic treatment of the disease, reducing the leucocyte count, had been expended on basic physiology and pathology, we might well be much nearer to rational treatment.—Sir Lionel Whitby, Whither Clinical Pathology? Trends and Opportunities, *Journal of Clinical Pathology*, May, 1951.

ACUTE GLOMERULONEPHRITIS FOLLOWING ADMINISTRATION OF RHUS TOXIN

REPORT OF A FATAL AND A NEAR FATAL CASE

Bertram Shaffer, M.D., Carrol F. Burgoon, M.D., Philadelphia
and
James H. Gosman, M.D., Indianapolis

Administration of extracts of poison ivy for active treatment of the acute dermatitis caused by this plant has been widely practiced. It is the purpose of this report to call attention to a variety of reactions, particularly serious kidney damage, which may occur following this treatment.

The plants which commonly produce this type of contact dermatitis belong to the family Anacardiaceae, and are Rhus Toxicodendron (poison ivy), Rhus diversiloba (poison oak), and Rhus Vernix (poison sumac).

Local and general reactions have been reported in patients given prophylactic or active treatment, orally or by injection, with extracts of these substances.[1] Intramuscular injections for prophylaxis against future attacks may cause local reactions at the site of injection, as well as constitutional and cutaneous reactions.[2] Oral administration, in an attempt at hyposensitization, produces various types of localized and generalized eruptions,[3] stupor, convulsions, and hyperpyrexia.[4] In patients with acute dermatitis to whom the extract was given intramuscularly as treatment, systemic reactions,[5] marked exacerbation and prolongation of the existing dermatitis [6] and hemorrhagic skin reactions [7] have been noted. Rytand [8] described seven patients with severe kidney damage following poison oak dermatitis, three of whom died.

We have recently observed a fatal reaction and a near-fatal reaction was brought to the attention of one of us (C. F. B.), both reactions occurring in patients in whom intramuscular injections of Rhus toxin were administered for the active treatment of the dermatitis. In these cases the dermatitis was exacerbated and, following a short latent period, the clinical symptoms and signs of acute glomerulonephritis developed. The use of this material for active treatment is widespread, and, for this reason, we feel these severe complications are worth reporting.

The Council on Pharmacy and Chemistry of the American Medical Association has warned of the potential dangers of these preparations.[9] It has pointed out that, in spite of numerous reports since 1925, the efficacy of these extracts administered parenterally for prophylaxis of Rhus dermatitis has never been established, and that while the oral desensitization method using very large doses of these substances is often effective, this method is cumbersome, time consuming, unpredictable, and fraught with discomfort and danger to the patient, and the extract should be administered only by an expert. The Council, furthermore, stated that the reports dealing with the treatment of acute dermatitis with these extracts are few in number and completely unconvincing as to their beneficial effects. Since from a theoretical point of view their use is unjustifiable, and since exacerbations of dermatitis have been known to result from this form of treatment, the report of the Council denounced the use of these preparations in the phylactic treatment of acute dermatitis. More recently Hoagland [10] in an excellently controlled study has thrown further doubt on the benefit to be derived from prophylactic injection of Rhus extracts.

REPORT OF CASES

Case 1.—J. M. R., a white man aged 61, was admitted to Skin and Cancer Hospital on Sept. 25, 1947. Two weeks preceding admission, pruritus, edema, and erythema of the face, hands, and arms developed a few hours after he weeded his garden. A series of four daily intramuscular Rhus toxin antigen injections was started the following day. On September 17, following the fourth injection, his dermatitis became markedly worse. Previous medical history revealed nothing of note except a severe case of Rhus dermatitis ten years previously.

Physical examination revealed a generalized scaling erythroderma with large purulent bullae on the feet and hands, a widespread folliculopustular eruption on the trunk, and pronounced edema of the entire face, hands, arms, and legs up to the knees. Temperature on admission was 100.2 F.; pulse, 80; respirations, 30, and the blood pressure was 150/90. The remainder of the physical examination was essentially normal. Laboratory studies of the blood on admission showed a hemoglobin value of 83% and 9,000 leukocytes with normal differential. Urinalysis revealed a specific gravity of 1.025, a trace of albumin, occasional white blood cells and a few hyaline casts. The bacteriologic culture of bullous fluid was negative for Staphylococcus albu and Staphylococcus aureus by coagulase test.

From the Skin and Cancer Hospital of Philadelphia, and the Department of Dermatology and Syphilology, Medical School of the University of Pennsylvania, Dr. Donald M. Pillsbury, Director.

Treatment consisted of debridement of the hands and feet, Burow's solution compresses, forced fluids, tripelennamine (pyribenzamine®) hydrochloride, and boric acid irrigation to the eyes.

By October 4, the condition of the skin had improved, and the pruritus, scaling, and edema of the face and hands had diminished. However, there was pronounced edema of the lower extremities up to the knees. On October 10, the patient complained of shortness of breath, urinary frequency, nausea, headache, and mild diarrhea. Physical examination revealed edema involving the legs, hips, and abdominal wall, and moist rales at the bases of both lungs. The blood pressure rose to 186/110. Laboratory findings were blood urea nitrogen, 43 mg. per 100 cc.; urinary output, 3,600 cc.; urine, a specific gravity of 1.030, a heavy cloud of albumin, occasional red and white blood cells, and a moderate number of fine and coarsely granular hyaline casts. The blood cell count showed only moderate leukocytosis. On the following day, the pruritus had increased, and erythema and urticaria appeared over the face and shoulders. In four days the urinary output fell to 700 cc. A phenolsulfonphthalein test showed 25% excretion in the first hour and 18% in the second. A Mosenthal test demonstrated limited urine concentration of from 1.015 to 1.017 in specific gravity. Serum albumin was 3.9 mg. per 100 cc. and globulin 2.3 mg. per 100 cc. The edema increased, blood pressure rose to 221/118, and the patient developed fleeting periods of mental confusion. The blood count showed a 5% eosinophilia. The patient became anuric, blood urea nitrogen rose to 105 mg. per 100 cc., and blood pressure reached a point beyond manometer readings. He died on October 21, twenty-six days after admission. A blood count done the day before death showed 9% eosinophilia.

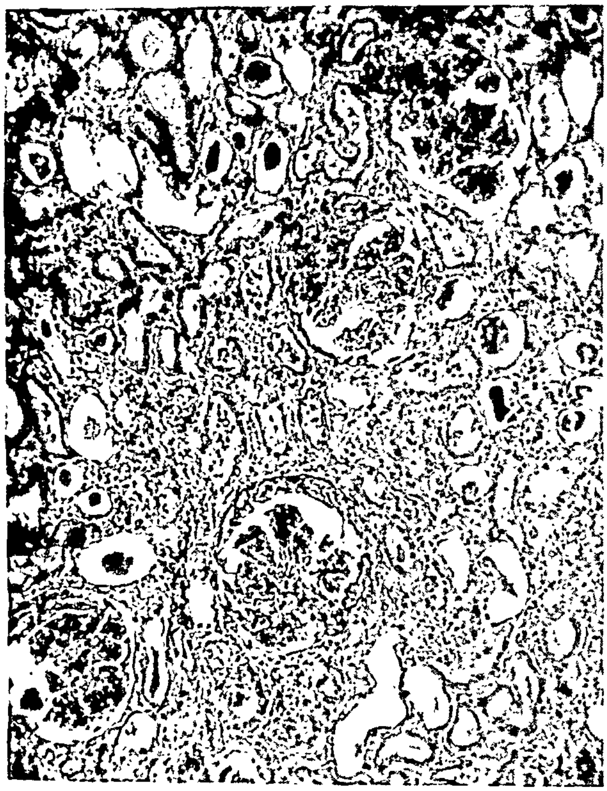

Fig. 1.—Microscopic section of kidney in case 1 showing the features of acute glomerulonephritis. These included swelling, bloodlessness, and coarsening of the glomerular tufts. Increase in nuclei with proliferation of the glomerular and capsular epithelium and adhesions are evident. Many tubules are distended, elongated, and contain casts. The lining cells show flattening and degeneration. The interstitial tissue is the site of edema and cellular infiltration.

Autopsy was limited to the kidneys. On opening the abdomen there was no evidence of peritonitis, and all organs appeared normal. Grossly, the kidneys cut with increased resistance; the capsule stripped easily leaving a relatively smooth, slightly granular surface. Petechial hemorrhages and small areas of necrosis were seen.

On microscopic examination (made by Dr. Warren F. Sheldon) the glomeruli showed the changes typical of acute glomerulonephritis. They were diffusely involved by an inflammatory process characterized by moderate swelling, nearly complete bloodlessness, and subdivision of the glomerular mass into several coarse club-like parts. The number of nuclei was greatly increased. This increase was due to proliferation of both capsular and endothelial lining cells and to infiltration by moderate numbers of leukocytes. Of the few capillaries that were open, many appeared to be plugged by agglutinated masses of red blood cells or similar-staining hyaline thrombi. The glomerular capsular epithelial lining showed active proliferation with many adhesions to the tuft. Well-formed "crescents" were common.

The tubules showed slight focal atrophy. Many were distended by casts of brightly eosinophilic hyaline material (probably protein). These casts extended the whole length of the nephron from the glomerulus to the tip of the pyramid but were larger in the loop of Henle and below. The tubular epithelium was often flattened. The proximal tubular epithelium stained irregularly and contained vacuoles. Many cells contained masses of coarse intracytoplasmic, brightly eosinophilic, hyaline droplets (probably protein). The interstitial tissue was moderately increased in amount, due largely to edema and mild leukocytic infiltration, mostly lymphocytes, plasma cells, monocytes, with variable numbers of polymorphonuclear leukocytes. The small arteries occasionally seemed swollen and contained leukocytes in and near the wall.

Case 2.—A. M., a white woman aged 42, was admitted to the Emergency Hospital in Doylestown, Pa., on May 16, 1947. Two weeks prior to admission she had contact with poison ivy, and within approximately 24 hr. typical acute contact dermatitis involving the hands, face, and forearms had developed. The patient received Rhus tox antigen intramuscularly at daily intervals for four days. After the first two injections the dermatitis became worse and generalized, but following the fourth injection the dermatitis appeared to be improving. Three days after the last injection the patient had a chill, temperature became elevated, and headache, anorexia, and nausea developed.

The patient was admitted to the hospital with temperature 100 F., pulse 110, respirations 26, and blood pressure 116/80. During the subsequent period of hospitalization, anorexia increased, and nausea and vomiting, restlessness, and edema of the face developed, blood pressure increased (180/100), oliguria developed (300 cc. in 72 hours after admission), blood urea nitrogen rose (56 to 65 mg. per 100 cc.) and red blood cells and albumin appeared in catheterized specimens of urine. On the 10th day of hospitalization with increasing urinary excretion, there was rapid clinical improvement. The patient was discharged on the 23rd day of hospitalization. The blood pressure and urine returned to normal within a period of six months and have remained normal to the present time.

COMMENT

The evidence that these patients had kidney disease is conclusive. It seems probable that the kidney disease was due to sensitivity to Rhus toxin.

The pronounced sensitivity of the patients to Rhus toxin was indicated by the history of a previous severe dermatitis venenata in case 1 and the exacerbation of the present dermatitis following injections of the Rhus extract in both cases. That the kidney complication was a sensitization phenomenon is suggested by the latent

period between the last injection of Rhus toxin and the first sign of kidney disease. In case 1 there was an associated increasing eosinophilia. The renal disease in both cases was an acute, rapidly advancing process rather than a chronic degenerative one, as evidenced by the fulminating clinical signs with concomitant laboratory changes.

Rytand [8] reported the appearance of renal disturbances in seven patients three days to two months after the onset of poison oak contact dermatitis. Three of these patients died, and of these, two had been given Rhus toxin for the active treatment of their dermatitis. Rytand and others [11] have also reported two cases of periarteritis nodosa with a renal involvement, following contact type plant dermatitis.

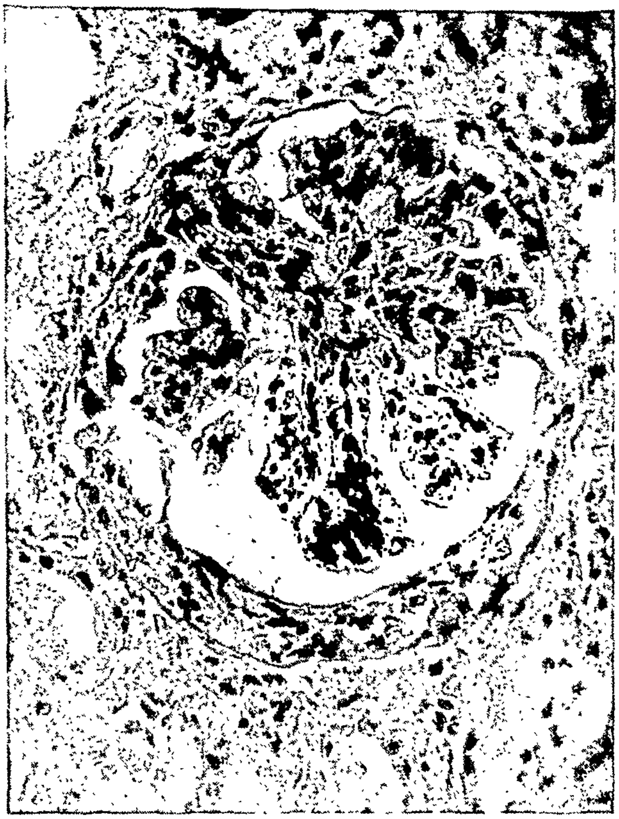

Fig. 2.—Enlargement of glomerular tuft in Figure 1, revealing the proliferation and inflammatory features in both the glomerular and capsular epithelium.

The chemical nature of the Rhus toxin has been extensively studied for the past 50 years.[12] The active principle is apparently a toxic oil with three active components and several innocuous concomitants as demonstrated by fractional distillation.[13] Hill and others [12] reported that at least one of the toxic principles was a catechol compound (urushiol).

Such relatively simple compounds may induce both epidermal sensitization and anaphylactic shock by acting as hapten allergens.[14] This process probably occurs through conjugation with the host's own protein.[15] It is thought that the active fraction of Rhus is a polyhydric compound which is oxidized to a quinone configuration before reacting with native protein to form a fully antigenic compound.[15a,b] A complete antigen of this type may produce sensitization of the entire organism as well as local epidermal phenomenon.[16] Proof of systemic sensitization with Rhus is demonstrated by recent studies in experimental animals in which sensitivity to poison ivy was passively transferred with serum as well as with cellular extracts of spleen.[16a]

Rich [17] has demonstrated that simple chemical compounds such as sulfonamides may induce an allergic reaction in the kidney manifested by glomerulonephritis or periarteritis nodosa. It is suggested that Rhus toxin may act as a hapten allergen in the same manner and also produce glomerulonephritis.

SUMMARY AND CONCLUSIONS

Two cases of acute glomerulonephritis occurring one week and four weeks after injections of Rhus toxin for the treatment of patients with dermatitis venenata due to poison ivy are reported.

In the fatal case, the associated eosinophilia, urticaria, and histological changes in the kidney indicate that the patient's death was a result of an allergic phenomenon.

Rhus toxin is a potentially dangerous hapten-type allergen which may induce systemic sensitization.

The administration of Rhus extracts is of no demonstrated value in the active treatment of plant dermatitis. Because of their great potential danger, it is felt that Rhus extracts should not be used in these cases.

Sphincter-Saving Resections of the Rectum.—Undoubtedly the most exciting development in the surgery of rectal cancer in recent years has been the attempt to revive sphincter-saving excisions in the radical treatment of this disease. Of course, it has always been the ambition of right-thinking surgeons to be able to excise malignant growths of the rectum without having to sacrifice the wonderful anal sphincter apparatus, but earlier experiences at the turn of the century with operations of this type had not been very happy and after a brief period of popularity they fell out of favor in this country and America, though still employed in Germany and Austria.

The present re-awakening of interest has been due to the important researches on the spread of rectal cancer by Cuthbert Dukes (1940) and Heinrich Westhues (1934). They have provided solid pathological grounds for believing that sphincter preservation is compatible with the requirements of radical surgery for most growths in the upper half of the rectum or rectosigmoid. Whether this is in fact so can only be decided by an extended trial in actual practice and that is now being undertaken in many centers in the United States and in Britain. —J. C. Goligher, Ch. M. Edin., F.R.C.S., Hunterian Lecture delivered at the Royal College of Surgeons of England, March 13, 1951, *Annals of the Royal College of Surgeons of England,* June, 1951.

CHRONIC VITAMIN A POISONING

REPORT OF A CASE

George Bair, M.D., New York

Hypervitaminosis A is a syndrome first described by Josephs in 1944.[1] Subsequently, there have been 13 additional cases reported.[2] Observers have noted the following characteristic manifestations of the entity: external cortical thickenings of the affected bones, pain and swelling over the long bones, irritability and fretfulness, and increased vitamin A concentration in the blood.

REPORT OF CASE

B. Z., a 28-month-old white child, was first seen by me on April 15, 1950, after he had been ill at home for two and one-half weeks. His main complaints were painful swellings of the left foot, right forearm, and temporal regions. He also complained of severe itching of the back and arms. At the onset, although limping, the child was able to get around, but within a few days the pain became so severe that he refused even to attempt to walk. Penicillin and aureomycin were administered during the first two days of the illness, but were discontinued because he became progressively worse.

Fig. 1.—Left foot, showing swelling in region of fifth metatarsal.

Past History.—The child had been a full-term, normal-delivery infant weighing 6 lb. 7 oz. (2.9 kg.) at birth. Five days post partum his mother died of virus pneumonia, so that he was brought up by grandparents. His feeding history was unusual in several respects. Since he rejected solids for the most part, his food was taken strained or mashed. He craved butter and ate large quantities of it. In addition, he showed a preference for milk, cheese, eggs, liver, carrots, tomatoes, and sweet potatoes. His appetite had been good until the onset of symptoms, after which he rejected all food. The vitamin intake was supposed to be 20 drops of percomorph liver oil daily. However, when the diagnosis became evident, requestioning disclosed that because of an error a considerably larger amount of oil had been given.

Seven weeks before the onset of symptoms, the child complained of itching in the back of his neck. During the following weeks the pruritus became more intense and spread down the back and arms. This was so troublesome that a doctor who was consulted thought it was an allergic condition.

Physical Examination.—Examination revealed a well-developed, well-nourished boy who appeared sick and in pain. The child seemed to have a stiff neck when sitting up. He was fretful and irritable. His face was puffy; the lips, in contrast, were dry and fissured. Thin serous fluid ran from the nose. Bilateral temporal swellings, larger on the left, were visible and palpable. A fusiform swelling covered the fifth left metatarsal. The dorsa of both feet were edematous, and the right forearm was swollen.

All swellings were hard and tender. Only one area, the outer aspect of the fifth left metatarsal, was hot and bluish in color. The entire body, even those parts which were not swollen, was tender to the touch. The tonsils were enlarged.

There was no palpable enlargement of spleen or liver. No abnormal masses were felt in the abdomen.

At no time during the illness did the temperature rise over 100 F.

Hemoglobin value was 79%; the red blood cell count was 4,900,000; the white blood cell count was 10,200; platelets 240,000; neutrophils: nonsegmented 6%, segmented 39%; eosinophils 2%, lymphocytes 45%, monocytes 7%, plasma cells 1%; hematocrit reading was 35.3; icterus index, two units; sedimentation rate (Westergren), 56 mm. in one hour (normal is up to 15 mm. in one hour). The findings in the urine were normal.

Blood vitamin A level on April 18, 1950, was 1040 I. U. (normal 50-150 I. U.).

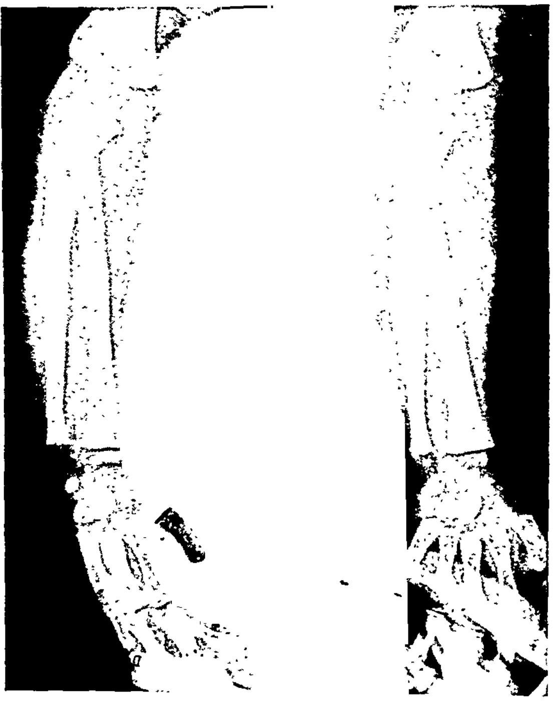

Fig. 2.—Right ulna, showing cortical thickening in the middle third of the shaft.

X-ray examination completed on April 15, 1950, revealed the following abnormalities:

Left Radius: Normal except for slight swelling of the soft tissues adjacent to the distal lateral aspect of the shaft.

Right Ulna: Smooth, homogenous, moderately dense external cortical thickening in the middle third of the shaft. The margins of this hyperostosis were smooth and merged imperceptibly with the marginal cortex. There was no evidence of destruction. Distinct soft tissue swelling was seen contiguous to the cortical thickening.

Dr. John Caffey assisted in the preparation of this paper.

Department of Pediatrics, New York Medical College, Flower and Fifth Avenue Hospitals.

[2] Toomey, J. A., and Morissette, R. A.: Hypervitaminosis A, Am. J. Dis. Child. 73:473 (April) 1947. Rothman, P. E., and Leon, E. E.: Hypervitaminosis A, Radiology 51:368, 1948. Dickey, L. B., and Bradley, E. J.: Hypervitaminosis A: Case Report, Stanford M. Bull. 6:345, 1948. Fried, C. T., and Grand, M. J. H.: Hypervitaminosis A, Am. J. Dis. Child. 79:475 (March) 1950. Caffey, J.: Chronic Poisoning Due to Excess of Vitamin A, Pediatrics 5:672, 1950.

Right Femur: Faint cortical thickening along the medial aspect of the middle third.

Right Fibula: Slight hyperostosis in the midshaft laterally.

Left Tibia: Cortical hyperostosis along the lateral and anterior aspects of the proximal end of the shaft. Adjacent soft tissue was swollen.

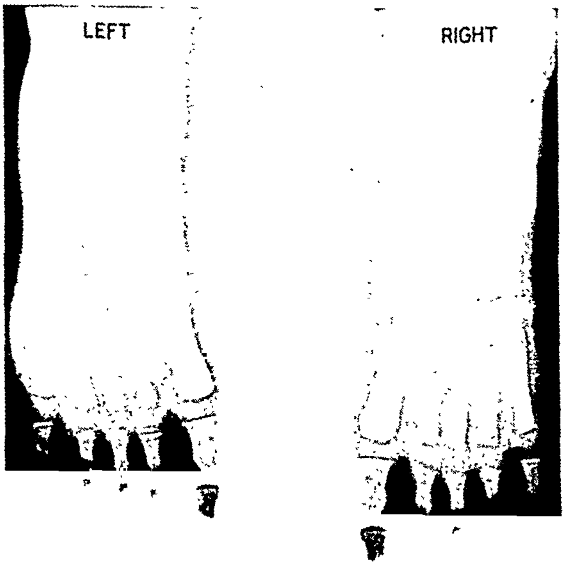

Fig. 3.—Metatarsal regions, both feet, showing lesions and soft tissue swelling over left fifth metatarsal.

Left Fifth Metatarsal: Moderately extensive cortical hyperostosis along the entire shaft. Considerable soft tissue swelling was present in this region.

New bone formation was also seen in the left third and fourth metatarsals and fourth right metatarsal.

Skull: Distinct periosteal new bone formation, less dense than the bones of calvarium, homogenous in character, and similar to hyperostosis present in the long bones. The largest patch of cranial hyperostosis was on the undersurface of the occipital bone extending to and on the left side of the foramen magnum. Smaller, more discrete areas of denser hyperostosis were present in each temporal region, and were more marked on the left side.

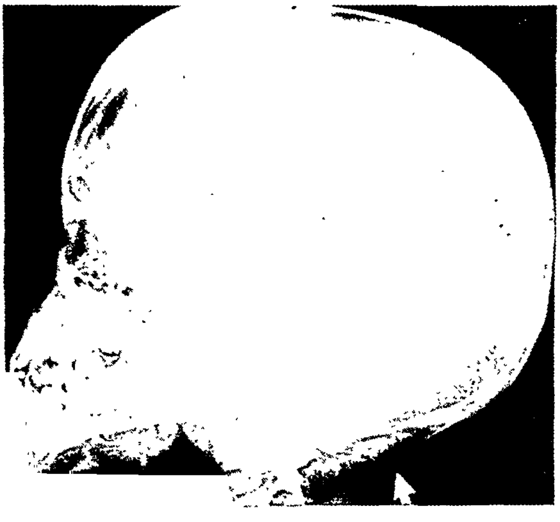

Fig. 4.—Skull, showing large patch of hyperostosis on undersurface of occipital bone.

Subsequent Course.—All vitamin supplements and excessive amounts of butter were eliminated from the diet. Within three days the child was able to walk, even though the metatarsal swelling had become more pronounced. The child appeared happy and seemed to be greatly improved. One month later, the metatarsal swelling was practically gone. The swellings of the forehead were still present, but were no longer painful or tender. In roentgen films made at the same time, all the hyperostoses except those in the skull had disappeared. Blood vitamin A level was 750 I. U.

COMMENT

Through a misunderstanding on the part of the grandmother, a teaspoonful of percomorph liver oil was given instead of 20 drops. Thus the child received in excess of 4 gm., or 240,000 units, of vitamin A daily during a period of at least three months. Prolonged continuous administration seems to be necessary before symptoms appear in children. Because of this, the administration for long periods of large doses of vitamin A in the treatment of skin diseases would seem to be a potentially dangerous procedure.

Although 14 cases have been reported, only two others showed swelling in the head. Neither of these cases showed as marked periosteal involvement as the one described above. The location of new bone formation on the undersurface of the occipital bone has never been reported previously. After one month, x-ray of the skull still revealed marked hypertostosis. Apparently new bone formation in this area persists longer than in other affected bones. Bony proliferation and high vitamin A levels were present for some time after the patient was otherwise normal.

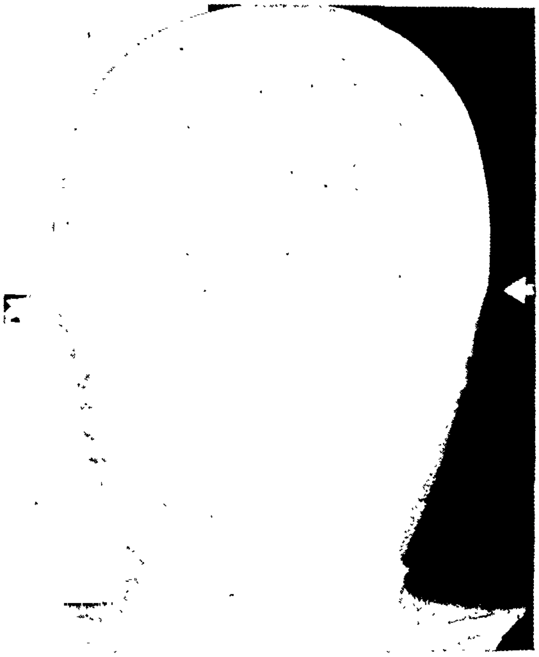

Fig. 5.—Skull, showing bilateral temporal hyperostoses.

SUMMARY

A case of hypervitaminosis A with the typical findings and an unusual cranial bone involvement is presented.

Because of the dangers of overdosage, caution is advised in the administration of vitamin A as a standard procedure in the feeding of healthy infants.

The prognosis in recognized cases is excellent after stoppage of excess vitamin A.

Leo Loewe, M.D., Brooklyn

An authoritative monograph by Emile Weil,[1] entitled "La ponction de la rate," marked the beginning of definitive findings in normal and pathological hematological conditions. This was followed by Moeschlin's splendid monograph,[2] which brought the subject up to date and served to stimulate others in furthering the study of spleen aspiration. Influenced by these researches, it was our intention to make a diagnostic study of spleen aspiration in hematological material that presented itself to us in hospital, clinic, and office. The scope of this contribution is limited to our own observations, since the literature has been adequately reviewed by Block and Jacobson.[3]

The time-honored examination of the peripheral blood, coupled with an adequate clinical investigation, sufficed to make possible the diagnosis of most hematological entities. In this manner, disorders of the red blood cells, white blood cells, and platelets were readily apparent. Anemias, erythrocytosis, agranulocytosis, leukocytosis, lymphocytosis, thrombocytopenia, and leukemia could thus, to a great extent, be readily resolved.

However, cryptic anemias, osteosclerosis, myelophthisic anemias, myelomas, Gaucher's disease, Niemann-Pick disease, and spent polycythemias were recognized with difficulty, mostly by implication. With the advent of bone-marrow aspiration, the solution to the problem was closer at hand.

As time went on, an impasse was reached in the diagnosis of extramedullary hematopoiesis, such as obtains in spent polycythemias and osteosclerotic anemias due to various causes. It was also difficult to differentiate between spent polycythemias and myelogenous leukemias. As a result, this led, oftentimes, to the erroneous conclusion that polycythemias resulted in myelogenous leukemias.

Also, it was taxing, many times, to resolve the causes of the various splenomegalies. Could we always be sure of an instance of Gaucher's disease which was limited to the spleen and escaped the bone marrow? Was it previously possible, before death, to postulate a diagnosis of lymphosarcoma of the spleen? How sure were we of the diagnosis of the various hemolytic anemias associated with splenomegaly? Thus, it became apparent that more knowledge concerning the hematological mechanisms was indispensable. It happens that the solution of the problem was not too far off. Moeschlin's[2] brilliant treatise on the subject was very stimulating, although Emile Weil[1] preceded this work and established the foundation for all future researches in spleen hemopathology.

METHOD OF SPLEEN ASPIRATION

Procedure.—The apparatus required are a 20-gauge needle, a dry syringe, and an alcohol sponge; no anesthesia is necessary. The operator stands at left side of patient and "shakes hands" with the spleen. The patient is told to stop breathing. The operator enters the spleen area close to the costal margin at the midclavicular line. He should aspirate rapidly, withdrawing the syringe and needle promptly. Then he should make a smear of aspirate (usually one drop of material).

The total time of procedure is from five to 10 sec.

As here noted, the procedure is innocuous. We attribute this element of safety to the fact that we limited ourselves only to spleens large enough to permit the abdominal approach, and did not use the thoracic approach sometimes employed by others. We never, to our knowledge, encountered the complication of puncturing the gastrointestinal tract. We believe this to be owing to the fact that a large spleen normally depresses the abdominal viscera in its vicinity. Also, bleeding tendencies were avoided in these large spleen cases. No extra preparation was required before a splenic aspiration. An enema might well be given as an extra precaution, but we never found it necessary. If aspiration did not yield sanguinous fluid, we never hesitated to repeat the procedure at once.

In one instance clear fluid which demonstrated pancreatic amylase was obtained. The mass in the left upper quadrant was not spleen, but later turned out to be a pancreatic cyst.

The approach here is mainly hematological, so that the unit of diagnosis was the cell rather than the tissue, thus delimiting the field between the hematologist and pathologist. The objective sought for in this contribution was adjunctive, not substitutive. Thus, an opportunity for earlier diagnosis, during life, could be achieved. The necropsy still remained the *sine qua non* for definitive, unequivocal diagnosis.

Splenectomy and necropsy serve to confirm the findings of spleen aspiration. This was found true in nine splenectomies and two necropsies resorted to in this study. Furthermore, 19 of these patients had lymph-node

aspirations; in two patients the conventional surgical lymph-node biopsy was done.

The following tabulation shows the distribution of conditions, based on clinical and hematological observations, in 105 cases of splenic aspiration.

Leukemia	
Eosinophilic	1
Acute myeloblastic	7
Chronic myelocytic	7
Chronic lymphatic	16
Lymphosarcoma cell	1
Lymphosarcoma	15
Hodgkin's disease	3
Osteosclerotic anemia	9
Polycythemia vera	7
Hemolytic anemia	3
Congenital hemolytic icterus	3
Banti's syndrome	3
Passive congestion of spleen	3
Cirrhosis of liver	3
Lymphnodulitis	3
Gaucher's disease	2
Giant lymphfollicular hyperplasia	2
Lipoid dystrophy	1
Gastrointestinal bleeding (postgastrectomy)	1
Hemangioma of spleen	1
Subacute bacterial endocarditis	1
Splenic vein thrombosis	1
Cooley's anemia	2
Hepatitis	1
Infection	1
Cardiac failure	1
No blood dyscrasia	6
Congenital telangiectasia	1
Total	105

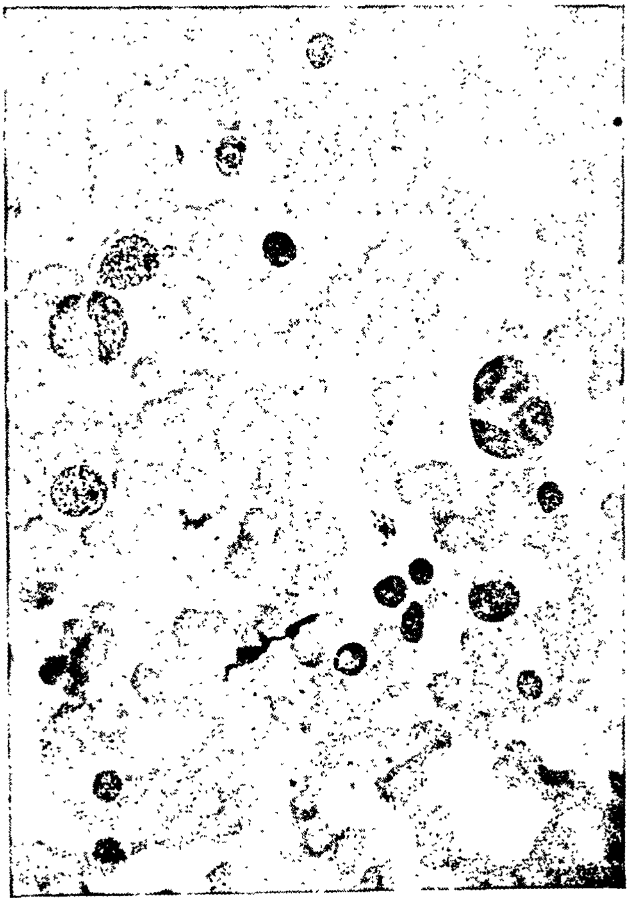

Fig. 1.—Spleen aspiration—Hodgkin's disease (Case L. C.). Monocytoid forms of Reed-Sternberg cells may be seen. Lymph-node aspiration was negative at this time.

The diagnosis in all cases was made by exposing the patients involved, whenever possible, to a battery of procedures as follows: (1) peripheral blood studies; (2) bone-marrow studies; (3) spleen aspiration; (4) lymph-node aspiration (where possible); (5) lymph-node biopsy (where possible); (6) pathological study of spleen after splenectomy, and (7) necropsy.

The types of cells noted above (Table 1) were found in this study and are but briefly described. Through the experience gained in this series of cases and a similar opportunity gained in viewing these cells in a number of cases with lymph-node aspiration (making a total of 206 experiences), we were able to orient ourselves adequately with the cytomorphological characteristics of these elements. After this study, we felt confident in setting down tentative criteria for the diagnosis of splenic aspirations in the different conditions.

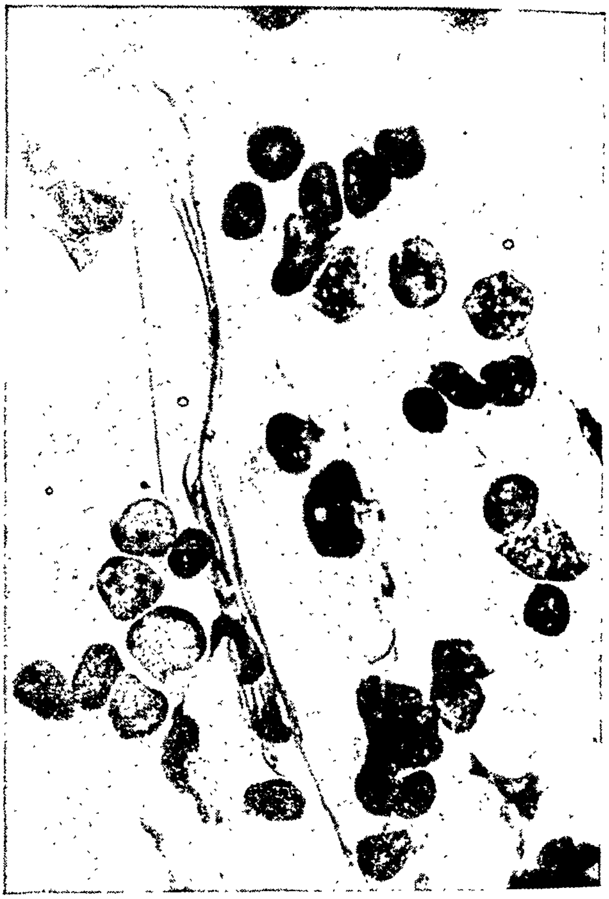

Fig. 2.—Lymph-node aspiration—lymphosarcoma (Case M. Y.). Large cell elements, scant cytoplasm, and absence of nucleoli can be seen. Type of cell above shown is the same as that found in spleen aspiration.

Criteria (cytomorphological) for the diagnosis of splenic aspirations have been briefly outlined in the previous table (Table 2). As will be noted, the following conditions have been characterized: (1) Hodgkin's disease, (2) lymphosarcoma, (3) lymphatic leukemia, (4) myelogenous leukemia, (5) giant lymphfollicular hyperplasia, (6) presence of extramedullary hematopoiesis, (7) absence of extramedullary hematopoiesis, and (8) Gaucher's disease.

REPORT OF CASES

Hodgkin's disease (three cases).—The unit cell is the Reed-Sternberg cell. The presence of an increase in monocytoid cells is suggestive (Fig. 1).

Patient L. C., a woman aged 56, presented pallor, enlarged nodes in the axillary and inguinal regions, a mass in the right upper quadrant, liver enlarged 1 fingerbreadth and spleen enlarged 2 to 3 fingerbreadths below the costal margin. On examination, the peripheral blood showed a hemoglobin value of 73%, 4,200,000 red blood cells per cubic millimeter, 7,400 white blood cells, with a differential count of 74% polymorphonuclear leukocytes, 23% lymphocytes, and 3% monocytes, and 3 + platelets.

Bone-marrow aspiration revealed a G:E ratio of 75:25, and 25% myelocytes, 10% metamyelocytes, 10% staff cells, and 55% polymorphonuclear leukocytes, with 3+ megakaryocytes.

Lymph-node aspiration showed 90% small and large lymphocytes and 10% polymorphonuclear leukocytes, with no Reed-Sternberg cells. Splenic aspiration revealed 20% polymorphonuclear leukocytes and 80% small and large lymphocytes, with 2+ Reed-Sternberg cells, 1+ monocytoid cells, 1+ macrophage cells, and 1 + reticulum cells.

Comment.—This case throws a glimpse at an interesting problem in spleen and lymph-node aspirations. An earlier lymph-node aspiration did not reveal definitive evidence of Sternberg-Reed cells, whereas a spleen aspiration done at the same time disclosed their presence. At a later time, a conventional surgical biopsy was positive for Hodgkin's disease. This emphasizes the point that the definitive findings of Hodgkin's disease not only vary in their onset, from lymph node to spleen, but also from one lymph node to another. This confirms the previously known nature of Hodgkin's involvement. In other words, one may state categorically that negative findings resulting from examination of a lymph node do not rule out the possibility of Hodgkin's disease in a given case. It is possible that the evidence may be present in another site or may make its appearance later on at the same site (Fig. 1).

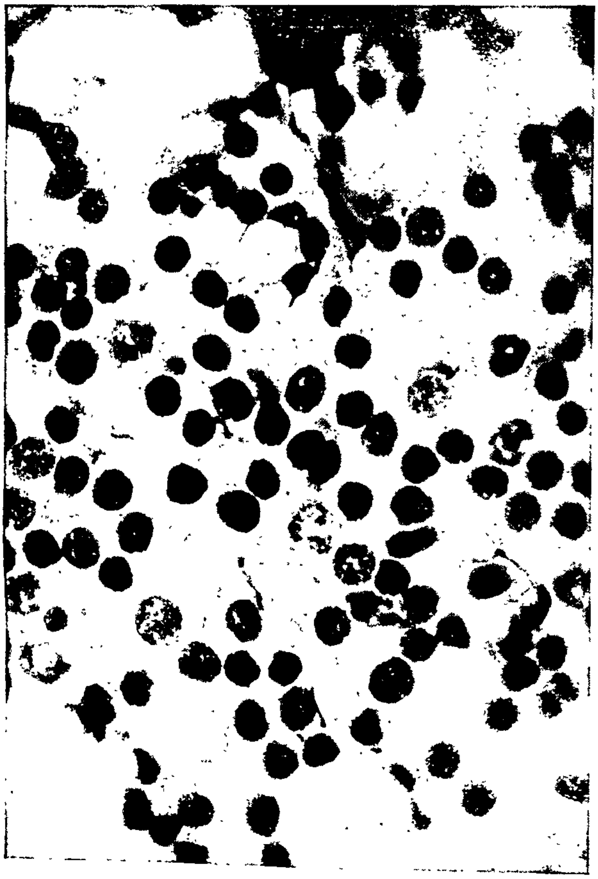

Fig. 3.—Spleen aspiration—chronic lymphatic leukemia (Case A. G.). Grumelée cell (typical mosaic or checkerboard or cartwheel appearance of nucleoplasm) can be seen.

Lymphosarcoma (15 cases).—The unit cell is the lymphosarcoma cell. It is usually the size of a large lymphocyte with scant cytoplasm and no nucleoloi. This cell is well depicted in the lymph node of case M. Y.

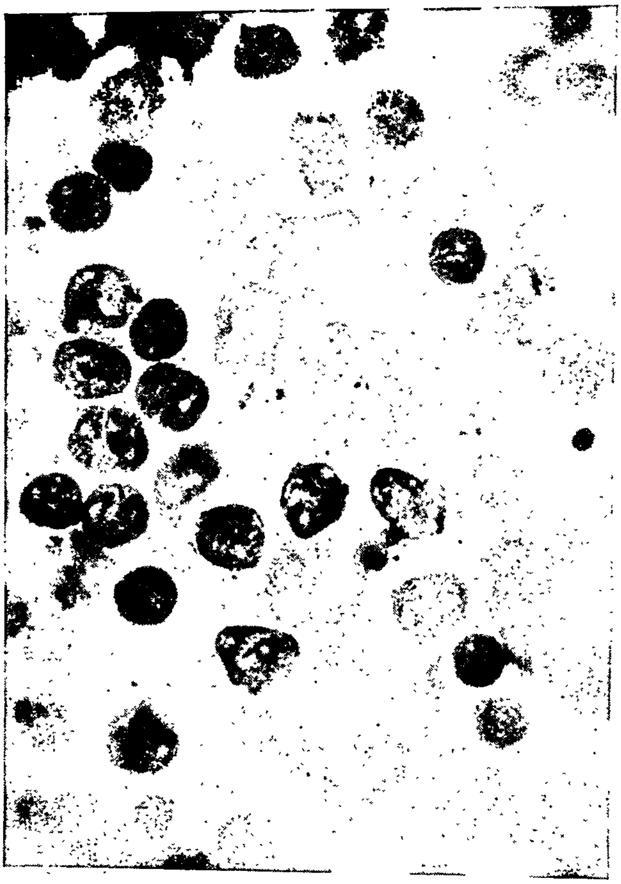

Fig. 4.—Spleen aspiration—acute myelogenous leukemia (Case J. L.). Myeloblasts and smudges may be seen.

Patient E. L., a man aged 57, presented marked pallor and weakness. The spleen was 3 to 4 fingerbreadths and the liver 2 to 3 fingerbreadths below the costal margin. Peripheral blood studies showed a hemoglobin value of 45% with 3,000,000 red blood cells; a white blood cell differential count of 72% polymorphonuclear leukocytes, 24% lymphocytes, and 4% monocytes, and 3 + platelets.

Bone-marrow aspiration revealed a G:E ratio of 20:80 and an L:E ratio of 75:25 and 25% myelocytes, 15% metamyelocytes, 20% staff cells, and 40% polymorphonuclear leukocytes.

Splenic aspiration showed 3 + small leukocytes; no lymphoblasts, Grumelée cells, or Reed-Sternberg cells, and many lymphosarcoma cells.

Comment.—Clinically, this case brought up for consideration various possibilities: (1) lymphocytic leukemia, (2) myelogenous leukemia, (3) Hodgkin's disease, (4) giant lymphfollicular hyperplasia, (5) lymphosarcoma.

Lymphatic leukemia was dismissed because of the lack of lymphocytosis in the peripheral study. Myelogenous leukemia was dismissed because of the absence of a left shift in the peripheral blood, bone marrow, and spleen. Hodgkin's disease was ruled out of consideration because of the absence of lymph-node enlargement and the absence of Sternberg-Reed cells in the spleen. Giant lymphfollicular hyperplasia was ruled out because of the absence of lymph-node enlargement, but here the question of lymphosarcoma loomed large, and the diagnosis was favored because of the presence of lymphosarcoma cells. However, it must be confessed that one cannot be dogmatic in these instances just on clinical grounds. The pathological diagnosis is still of paramount importance in distinguishing between the two. The rapid deterioration of the patient both clinically and hematologically favored the diagnosis of lymphosarcoma.

Lymphatic Leukemia (16 cases).—Chronic Lymphatic Leukemia: The unit cell is the Grumelée cell (Fig. 3). It has a typical checkerboard appearance.

Acute Lymphatic Leukemia: Here the unit cell is the lymphoblast. This cell is usually endowed with nucleoli. This point is very helpful in contradistinction to their absence in lymphosarcoma.

Patient A. G., a woman aged 62, was admitted with moderate pallor, and purpura of the lower extremities. She presented enlarged nodes in the axilliary, inguinal and cervical regions. The spleen was enlarged to from 3 to 4 finger breadths below the costal margin and the liver was enlarged to 2 finger breadths below the costal margin. Peripheral blood studies showed a hemoglobin value of 67% with 3,480,000 red blood cells, 576,000 white blood cells, 300,000 platelets, 10% lymphoblasts, 83% lymphocytes, and 7% polymorphonuclear leukocytes. Bone-marrow aspiration showed a G:E ratio of 95:5; G:L ratio of 15:85, and 3 + megakaryocytes, and 3 + smudge cells.

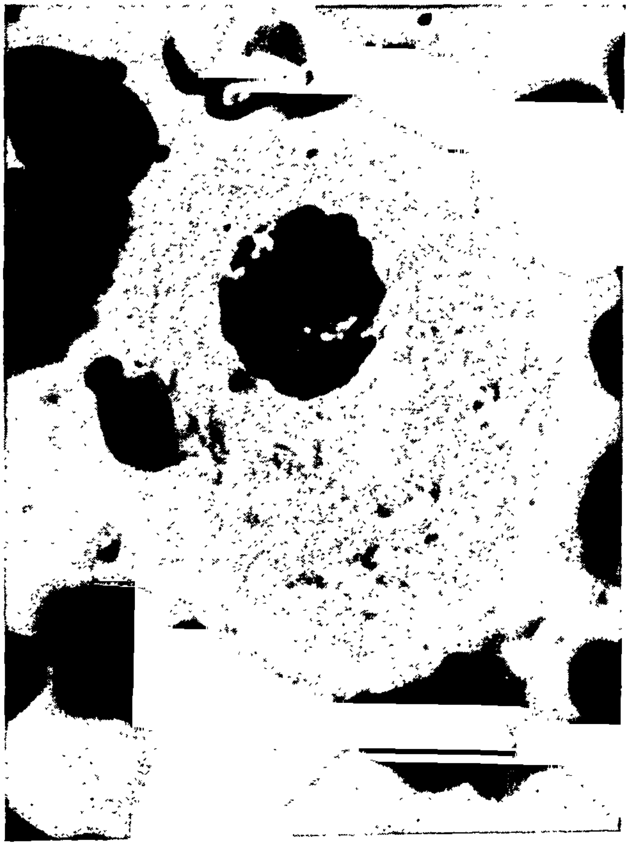

Fig. 5.—Spleen aspiration—Gaucher's disease (Case B. L.). Detailed study of cell can be noted. Here cytoplasmic structure is fibrillary as contrasted to the foam-like cytoplasm of the Niemann-Pick cell.

Lymph-node aspiration revealed 10% small lymphocytes, 80% Grumelée cells, and 10% lymphoblasts.

Splenic aspiration revealed 5% lymphoblasts and 95% Grumelée cells.

Comment.—The splenic aspiration did not reveal any information not already noted in the peripheral blood or lymph-node aspiration studies. Suffice it to say that lymphoblasts made their appearance in this case in all three media. This case is revealing in that it sheds light on the parallelism that occurs in these tissues, very much unlike that noted, for instance, in Hodgkin's disease, in which the degree of involvement is so variable in one site as compared to another.

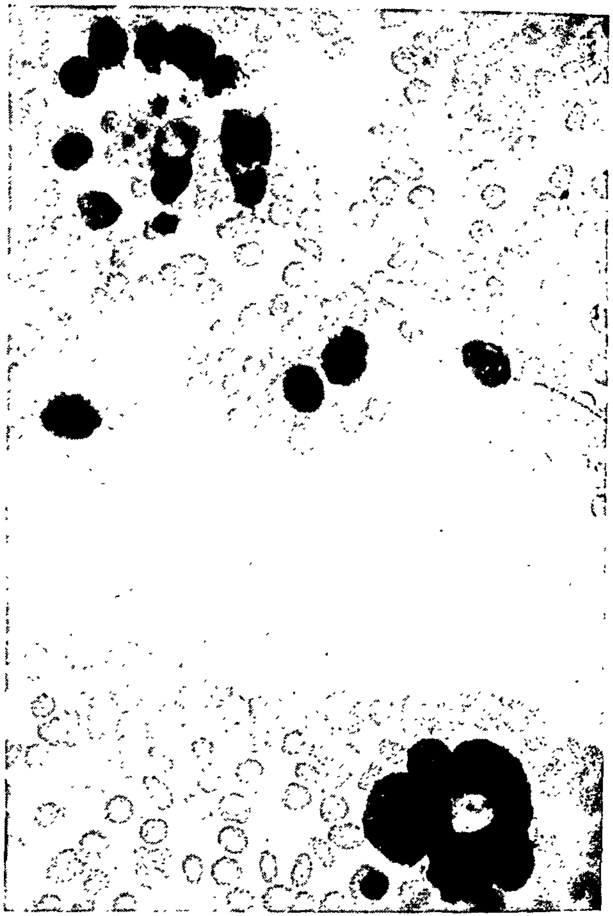

Fig. 6.—Spleen aspiration—spent polycythemia (Case L. G.). Large cluster of nucleated red blood cells above and megakaryocyte below can be seen.

Myelogenous Leukemia (seven cases).—The unit cell is the myelocyte in the chronic form and the myeloblast in the acute form (Fig. 4).

Patient A. B., a woman aged 50, was admitted with pallor and fever and presented extreme adenopathy, ascites, spleen enlarged 4 +, and liver enlarged 3 +. Studies on the peripheral blood showed a hemoglobin value of 66%, 3,600,000 red blood cells, 160,000 white blood cells, with a differential count of 5% myeloblasts, 60% myelocytes, 10% metamyelocytes, and 20% staff cells. Bone-marrow aspiration revealed 20% myeloblasts, 30% myelocytes, 10% metamyelocytes, 20% staff cells and 20% polymorphonuclear leukocytes, and *no* megakaryocytes (none on smear). The lymph-node aspiration and the splenic aspiration showed myeloblastosis (myeloblasts and myelocytes).

Comment.—The peripheral blood and bone-marrow, lymph-node, and splenic aspirations revealed essentially the same findings. This sheds light on the parallelism already noted in the case of lymphatic leukemia. Diagnostically, therefore, the spleen aspiration here serves a small purpose.

Giant Lymphfollicular Hyperplasia (two cases).—The picture is the same as that noted in lymphosarcoma.

Gaucher's Disease (two cases).—A case is presented as follows:

Patient B. L., a man aged 32, presented pallor, subicteric tint to the sclerae, and conjunctival pingueculae. The spleen was enlarged 4 to 5 fingerbreadths below the costal margin, and the liver extended 3 fingerbreadths below the costal margin. There were a few cervical nodes present. The splenomegaly was noted 20 years previously when the patient was aged 12 years, and the diagnosis was made then.

On study, the peripheral blood showed a hemoglobin value of 80%, and 5,000,000 red blood cells, 6,000 white blood cells, with a differential count of 68% polymorphonuclear leukocytes, 2% eosinophils, 27% lymphocytes, and 3% monocytes, and 100,000 platelets.

Bone-marrow aspiration revealed a G:E ratio of 60:40 and many Gaucher cells. Splenic aspiration showed many Gaucher cells (Fig. 5).

TABLE 1.—*Description of Cell Types Noted in Spleen Aspirates in this Study*

Cell Type	Frequency	Occurrence	Description
Small lymphocyte	85%	Normal	Same as in peripheral blood
Large lymphocyte	15%	Normal	Same as in peripheral blood
Reticulum cell	Occas.	....	Large nucleus (2 to 3 × size of small lymphocyte) surrounded by irregular cytoplasmic processes
Syncytial cell	Occas.	....	Groups of reticulum cells in masses with common bluish cytoplasmic background
Grumelée cell (Fig. 3)	Many	Lymph. leuk.	Lymphoid elements with checkerboard nucleus
Lymphoblasts	Occas.	Normal inflammations	Lymphoid elements with nucleoli
I. M. cells	Many	Infectious mononucleosis	Large lymphoid elements with indented nucleus and bluish cytoplasm
Myeloblasts (Fig. 4)	Many	Myelosis	Same as in peripheral blood
Monocytoid cells	Occas.	Hodgkin's disease	Like monocytes in peripheral blood occas. with more than one nucleus, Reed-Sternberg cells
Erythroid elements	Many	Extramedullary hematopoiesis, osteosclerotic anemia, spent polycythemia	Same as those seen in peripheral blood and bone marrow

Comment.—This case shows the benignity of Gaucher's disease. The patient was active all his life, but in the last six months found that the mass in his left side of the abdomen was interfering with his daily routine. The spleen was removed because of size.

It is interesting to note that the spleen was definitely more involved than the bone marrow. It seems possible, therefore, that a diagnosis may sometimes be delayed if the bone marrow alone is examined. Splenic aspiration, therefore, serves a definitely useful purpose in Gaucher's disease.

Extramedullary Hematopoiesis.—It is best that we define this term as used in this study. This serves to identify the presence of immature erythrogenetic elements, immature myeloid elements, or megakaryocytes (Fig. 6). Furthermore, the presence of lipoid or other histiocytic components may be included under this category. Such conditions as Gaucher's disease, Niemann-Pick disease, Hand-Schüller-Christian disease and Lederer-Siewe disease may thus be mentioned here.

It is well to stress the significance of extramedullary hematopoiesis. It appears, we believe, as a compensatory phenomenon in response to a failing marrow (osteosclerotic, myelosclerotic, myelophthisic).

Thus it is most frequently present in osteosclerotic anemia and spent or late polycythemia.

TABLE 2.—*Tabulation of Criteria in Splenic Aspirations*

I. Hodgkin's disease
  A. Reed-Sternberg cells
  B. Increase in monocytoid cells
  C. Presence of eosinophiles
  D. Polynuclears present from 10 to 50
  E. Increase in large lymphoid elements (normal ratio of small to large lymphoid elements S:L is 90:10; here S;L is 30:70)
  F. Reticulum cells—1+ to 2+
II. Lymphosarcoma
  A. Large lymphoid elements increased (S:L is 10:90). These have large nucleus, rare nucleoli and scant cytoplasm (no checkerboard appearance)
  B. Mitotic figures are prominent
  C. Occasional hemohistioblasts seen
III. Giant lymphfollicular hyperplasia
  Same as lymphosarcoma with addition of occasional monocytoid and small lymphoid elements
IV. Lymphatic leukemia
  A. Chronic
    1. Small lymphoid elements (Grumelée cells) increased (S:L is 90:10). These cells are medium-sized and have a checkerboard appearance
    2. Large lymphoid elements are rare
    3. No polynuclears seen
  B. Acute
    1. Few Grumelée cells seen
    2. Preponderance of lymphoblasts with nucleoli
    3. Rare mitotic figures
  C. Subacute
    1. Grumelée cells and lymphoblasts equal in number
V. Myelogenous leukemia
  A. Chronic—Myelocytosis (90% of cells present)
  B. Acute—Myeloblastosis (90% of cells present)

VI. Extramedullary hematopoiesis present	Myeloid	Erythroid	Lymphoid	Lipoid, Gaucher Niemann-Pick	Megakaryocytic
A. Osteosclerosis					
1. Early polycythemia	+	+	—	—	+
2. Late polycythemia	+	+++	—	—	+++
B. Leukemia with myelosclerosis...	+++	±	—	—	—
C. Myelogenous leukemia	+++	±	—	—	±
D. Lymphatic leukemia	—	—	+++	—	±
E. Osteosclerotic anemia	++	++	—	—	+
F. Gaucher's disease	—	—	—	+++	—
G. Niemann-Pick disease	—	—	—	+++	—
VII. Absence of or minimal extramedullary hematopoiesis					
A. Familial hemolytic anemia....	—	—	—	—	—
B. Acquired hemolytic anemia....	—	—	—	—	—
C. Cooley's anemia	—	—	—	—	—
D. Sickle cell anemia...............	—	—	—	—	—

Spent Polycythemia Versus Leukemia.—The following case is an illustration.

Patient L. G., a woman aged 38, presented anemia, inability to walk, an enlarged spleen 4 to 5 fingerbreadths below the costal margin, and an enlarged liver about the same size. There was a past history of polycythemia of 10 years' duration followed by hemiplegia. The peripheral blood showed a hemoglobin value of 58%, 3,007,000 red blood cells, 7,650 white blood cells, and 200,000 platelets.

Bone-marrow aspiration showed sparse marrow, relative erythroblastosis, smudges, and toxic elements.

Splenic aspiration revealed extramedullary hematopoiesis with 2 + erythrogenesis, and 1 + leukogenesis.

Necropsy showed erythroblastosis and a leukemoid reaction in all the reticuloendothelial organs.

Comment.—This case points out the important relationship of osteosclerosis to splenic hematopoiesis in a case of spent polycythemia of 10 years' duration. Also, one takes a glimpse at nature's effort of "treating" polycythemia vera in its own way, by producing a space-consuming lesion in the bone marrow, mediated through a progressive fibrosis and resultant osteosclerosis. This case also brings to the fore the old controversy of polycythemia vera and leukemia. Does one transform itself to the other? Splenic aspiration, as exemplified in this case, brings out the inherent erythrogenetic quality (secondary to complicating osteosclerosis) as opposed to a primary leukogenetic quality expressed in a leukemic process. We feel that our experience with splenic aspiration helped us to better understand this controversial issue.

Absence or Minimal Hematopoiesis.—Contrary to our preconceived ideas, we were surprised to find little or no hematopoiesis in the hemolytic anemias. This was true in all hemolytic anemias, Cooley's anemia and, undoubtedly, in sickle cell anemia.

Patient G. P., a woman aged 36, presented anemia, icteric tint to sclerae, and a spleen enlarged to below the umbilicus; splenectomy was done.

Studies on the peripheral blood revealed a hemoglobin value of 40%, and 1,770,000 red blood cells, 300,000 platelets, and 7,300 white blood cells, with a differential count of 78% polymorphonuclear leukocytes, 16% lymphocytes, and 6% monocytes.

Bone-marrow aspiration revealed a G:E ratio of 40:60 and an E:N ratio of 70:30 and 3 + megakaryocytes, 36% myelocytes, 18% metamyelocytes, 18% staff cells, and 28% polymorphonuclear leukocytes.

Splenic aspiration showed no evidence of erythrogenesis, leukogenesis, or platelets. Pathologist's report of spleen revealed "no evidence of hematopoiesis—a diagnosis compatible with hemolytic icterus."

Comment.—This is an instance of the lack of hematopoiesis (extramedullary) in a case of proven hemolytic icterus. The pathological report of the removed spleen confirmed the diagnosis. It is interesting to note that the lack of hematopoiesis is a constant feature in the hemolytic anemias. Thus, we are not surprised to discover similar features in Cooley's anemia and sickle cell anemia. This finding affords us another point in a differential between the splenomegaly of hemolytic origin as compared to those of osteosclerotic origin. As a matter of fact, it can be stated categorically that the presence of hematopoiesis in a spleen is proof against a diagnosis of hemolytic anemia. This finding was concurred in by *Moeschlin.*[4]

COMMENT

Spleen aspiration has become an important addition to our diagnostic armamentarium in hematological conditions. It is interesting to note in this connection (Table 3) that in the 105 cases studied with spleen aspiration it was possible to make an adequate diagnosis by blood alone in 29 cases. In 32 cases the combined bone-marrow and peripheral blood studies led to the diagnosis. In 102 out of 105 cases, the combined spleen aspiration with the bone-marrow and peripheral blood studies led to the correct diagnosis. Thus, it may be seen that at the present time the hematologist has at his command the utilization of four avenues of approach to a clinico-hematological problem, i. e., the blood, the bone-marrow, the lymph-node, and the splenic aspiration. Certain conditions previously difficult to diagnose ante-mortem become very easily identified. These are (1) osteosclerotic anemia, (2) extramedullary hematopoiesis, (3) Gaucher's disease (especially if absent in the bone marrow), and (4) spent polycythemia.

Again, it is generally accepted that splenectomy is contraindicated if the spleen shows hematopoiesis. In these circumstances, it is imperative to ascertain whether extramedullary hematopoiesis is absent before contemplating splenectomy. This can easily be done by splenic aspiration. Thus, the surgeon has still another precaution to observe before attempting splenectomy.

SUMMARY

A series of 105 splenic aspirations is reported and analyzed, and the technique of splenic aspiration is described. Criteria for the diagnosis of hematological conditions by splenic aspiration are outlined. Diagnosis by splenic aspiration is made possible in conditions heretofore identified only at operation (splenectomy) or necropsy.

TABLE 3.—*Comparative Diagnostic Value of Studies of Peripheral Blood, Bone-Marrow, and Splenic Aspiration in 105 Cases with Splenomegaly*

Diagnosis Established by	No. of Patients	Percentage Correct Diagnosis
Peripheral blood alone	29	27.6
Bone marrow and peripheral blood combined	32	30.5
Splenic aspiration, bone marrow and peripheral blood	102	97.2

Another means of studying extramedullary hematopoiesis is offered. Splenic aspiration as a precautionary measure prior to splenectomy, to exclude hematopoiesis, is presented. Hemolytic icterus, Cooley's anemia, sickle cell anemia, and other hemolytic anemias do not present significant splenic hematopoiesis.

645 Ocean Ave.

Thirst.—Two theories have been advanced to explain the mechanism by which the sensation is aroused. . . . According to one view, thirst is due simply to the drying of the pharyngeal mucous membrane, the salivary glands being given a role in the regulation of the water balance of the body. When the water content of the body falls below a certain level salivary secretion is depressed, the consequent drying of the mucous membrane of the throat then elicits the characteristic sensation. If such a view is correct, drying of the pharyngeal mucosa from whatever cause should cause thirst. . . . According to the other view, thirst is a sensation resulting from changes in blood composition, probably to a rise in its osmotic pressure, which stimulates the afferent nerve endings; or acts perhaps upon central nervous structures. . . . Neither theory alone explains all the experimental facts. It appears that the factors concerned in the production of thirst are both local and general. The importance of a rise in the osmotic pressure of the blood in causing the sensation is suggested by the experiments of Verney on water diuresis, for it is not unreasonable to suppose that thirst and the control of the water balance of the body through the antidiuretic principle of the pituitary are parts of the same mechanism.—Charles Herbert Best, M.D., and Norman Burke Taylor, M.D., The Physiological Basis of Medical Practice, Baltimore, The Williams & Wilkins Company, 1950, p. 606.

COLLECTING SPECIMENS FOR THE LABORATORY DEMONSTRATION AND ISOLATION OF FUNGI

Libero Ajello, Atlanta

Clinical laboratory procedures in medical mycology are directed toward the demonstration and isolation of pathogenic fungi occurring in body tissues and fluids. The diagnostic laboratory, however, cannot function unless adequate specimens, properly collected and handled, are received.

This paper has been prepared to assist clinicians in the collection of appropriate specimens from patients suspected of having mycotic infection. In general, the procedures involved are simple, and no elaborate equipment is required.

The types of specimens needed to demonstrate these fungi and to isolate them from clinical materials will be described for the following groups of fungus infections, and for each specific disease.

SUPERFICIAL MYCOSES

These are fungus infections confined to the outermost layer of the skin and hair. The diseases included in this category are (1) erythrasma, (2) piedra, (3) tinea nigra, (4) tinea versicolor and (5) trichomycosis axillaris.

The mycotic nature of erythrasma, tinea nigra and tinea versicolor is established by the microscopic examination of skin scrapings obtained from suspected skin lesions. The affected area is prepared by a swabbing with a sponge soaked in 70% alcohol. This washing serves to remove dirt particles and any medication that would make microscopic examination difficult. After drying, the lesion is scraped with a sterile scalpel. The scales so obtained are placed in a small, sterile Petri dish and sent to the laboratory with all necessary data. For mailing to an outside laboratory, scrapings should be deposited on a piece of clean white paper that is carefully folded in the form of a packet to guard against loss of the material.

In suspected cases of trichomycosis axillaris, hairs are clipped from the axillary or pubic region, depending on the site of infection, and the specimen is sent to the laboratory in a Petri dish or a folded piece of paper.

In piedra, a mycotic infection of the hair of the scalp and beard, hairs are clipped from the areas involved and sent to the laboratory in a similar manner.

Cultures are not made in cases of erythrasma, tinea versicolor, and trichomycosis axillaris, as media have not yet been developed for isolating the causative agents. Their diagnosis is made solely on the basis of clinical impression and the demonstration of fungus elements in scrapings.

CUTANEOUS MYCOSIS

In this category are placed all those mycotic infections that involve the skin and hair to a greater extent than do the infections classified as superficial mycoses. These diseases, known as the dermatophytoses, include the following: (1) tinea pedis (athlete's foot); (2) tinea corporis (ringworm of the body); (2) tinea capitis (ringworm of the scalp); (4) tinea cruris ("jock itch," ringworm of the groin); (5) onychomycosis (nail infection); (6) candidiasis (moniliasis), and "thrush," paronychia and vaginitis.

In lesions involving the skin and nails, scrapings are obtained with a scalpel after careful washing of the site with alcohol. In ringworm infections of the smooth skin, it is important to collect the specimen from the active border of the lesions. Fungi grow in a centrifugal manner from the original point of infection and, as the fungus advances, a circular lesion is produced.

Hairs from suspected cases of tinea capitis are plucked out with tweezers. They are best obtained from the center of patches of infection that contain the stubs of infected hairs.

In scalp ringworm caused by species of Microsporum, the infected hairs fluoresce with a bright yellow-green color when exposed to ultraviolet light in a dark room. One can take advantage of this phenomenon by plucking the fluorescent hairs, thus insuring that only the infected hairs are collected and making isolation of the causative agent more certain. It is well to remember, however, that, in tinea capitis due to the trichophytons, infected hairs do not fluoresce brightly. Hairs from suspected lesions should be collected for culturing and microscopic examination regardless of the reaction to ultraviolet irradiation.

Skin and nail scrapings and hairs may be forwarded to the diagnostic laboratory in sterile Petri dishes or paper packets.

In suspected cases of Candida (Monilia) albicans infection, scrapings from the affected areas should be directly smeared on clean slides and, after drying, sent to the laboratory. In addition, several tubes of Sabouraud's dextrose agar should be inoculated with the material. Cotton swabs are not recommended for mailing, as they dry out in transit and hinder or even prevent the demonstration and isolation of fungi.

SUBCUTANEOUS MYCOSES

In this group are found the following diseases: (1) chromoblastomycosis; (2) mycetoma; (3) rhinosporidiosis, and (4) sporotrichosis. From this group of infections, clinical material of the following types may be used for laboratory examination: (1) pus from open abscesses; (2) exudate from draining sinus tracts; (3) material aspirated from subcutaneous abscesses and unopened sinus tracts, and (4) tissue taken for biopsy.

Such material should be placed in sterile vials or test tubes or, if mailed, inoculated on suitable media. There is an exception to this rule: scrapings and biopsy material from suspected rhinosporidiosis should be examined directly or fixed for histological examination. Media are not available for the culturing of the causative agent, Rhinosporidium seeberi.

SYSTEMIC MYCOSES

Systemic mycoses are caused by organisms that invade and attack the internal organs of the body, such as the lungs, liver, spleen, and kidneys. It must be remem-

---

From the Laboratory Services, Communicable Disease Center, Public Health Service, Federal Security Agency.

bered, however, that cutaneous manifestations of these diseases do occur, and specimens in such instances are collected in a manner similar to that described for the cutaneous mycoses. The systemic human fungus infections are (1) actinomycosis (caused by Actinomyces bovis), (2) North American blastomycosis, (3) South American blastomycosis, (4) candidiasis (moniliasis), (5) coccidioidomycosis, (6) cryptococcosis (torulosis), (7) geotrichosis, (8) histoplasmosis, and (9) nocardiosis (caused by Nocardia asteroides).

Materials for laboratory examination in systemic diseases are obtained from such varied sources as blood, spinal fluid, sputum, exudates from draining sinuses and abscesses, sternal marrow, scrapings from edges of ulcers and abscesses, aspirated fluid from subcutaneous abscesses and sinus tracts, and tissue taken for biopsy.

These materials should be placed in sterile vials, Petri dishes or test tubes for transfer to the laboratory. For mailing purposes, they should be inoculated on suitable media. Smears may also be made.

Peripheral blood, spinal fluid, sternal marrow and aspirated fluids should, of course, be collected with strict sterile precautions and inoculated directly onto appropriate media and/or placed in suitable sterile containers prior to transfer to the laboratory.

LABELING OF SPECIMENS

To facilitate the work of the diagnostic laboratory the following data should accompany all specimens submitted: (1) patient's name, age, and sex; (2) hospital or other number assigned to the patient or specimen; (3) name and address of the physician or other official to whom laboratory report is to be sent; (4) type of material submitted and date collected, and (5) suspected disease.

This last item, the citing of the suspected mycotic disease, is very important, as it serves to guide the laboratory in the examination of the specimen. For example, in suspected cases of actinomycosis, cultures are made on special media and incubated anaerobically. Unless A. bovis is suspected as the causative agent, fungus cultures routinely are incubated aerobically.

MAILING OF SPECIMENS

For best results, only agar cultures should be mailed to a laboratory for mycological examination. With the exception of such materials as skin scrapings, nail clippings and hairs, most clinical specimens are valueless by the time they reach the laboratory. While in transit, sputum, urine, exudates from lesions, bronchial washings and biopsied tissue usually become so quickly overgrown with saprophytic organisms that the demonstration and isolation of any pathogenic fungus originally present are rendered impossible. Clinical materials of this type should be sent to the laboratory only as a last resort, when media are not available and even then in rubber-stoppered vials tightly sealed and carefully wrapped for mailing.

When cultures are forwarded to a reference diagnostic laboratory, it is advisable to mail only pure and selected fungus cultures. If several different fungus species appear in a tube, only those suspected of being pathogenic should be subcultured to fresh tubes and mailed. Laboratory workers should be familiar with the most common saprophytic fungi, members of such genera as Alternaria, Aspergillus, Penicillium and Rhizopus, and should discard them when they appear in their cultures, unless there are specific grounds for considering them pathogenic in any given instance.

To facilitate the handling of cultures by the diagnostic laboratory, it is recommended that test tubes of standard size (18 by 150 mm.) be used. Odd-sized tubes and bottles are inconvenient to handle and present storage problems. Since the growth of many fungi is inhibited in screw-capped tubes, all cultures should be cotton-plugged. Test-tube cultures must always be wrapped individually in cotton or paper before being placed in the mailing container. The free space in the mailing tube should then be packed with sufficient cotton or other material to prevent breakage. Material obtained under sterile conditions, such as blood, spinal fluid, and aspirated pus, may, if necessary, be shipped by mail, provided that they are collected in sterile, tightly sealed vials or tubes. Of course, such containers must be packed carefully.

Petri-dish cultures should never be sent through the mail as they almost invariably break in transit; neither should cotton swabs be mailed, since they usually become desiccated before arrival at the laboratory.

ISOLATION MEDIA

The following formulas of media are suggested for the primary isolation of pathogenic fungi:

1. *Sabouraud's Agar*

Purpose.—Isolation of most pathogenic fungi.

Composition.—The formula follows.

Dextrose	40.0 gm.
Peptone	10.0 gm.
Agar	15.0 gm.
Distilled water	1,000.0 ml.

Procedure.—Dissolve ingredients in a water bath; place 8 ml. in an 18 by 150 mm. test tube. Sterilize by autoclaving 10 minutes at 120 C., and slant. This medium is prepared in dehydrated form by several companies.

2. *Thiamine-Dextrose Agar*

Purpose.—Isolation of Trichophytons of the faviform group, including Trichophyton violaceum.

Composition.—The formula follows.

Dextrose	40.0 gm.
Peptone	10.0 gm.
Thiamine	0.001 gm.
Agar	15.0 gm.
Distilled water	1,000.0 ml.

Procedure.—Dissolve ingredients in a water bath; place 8 ml. in an 18 by 150 mm. test tube. Sterilize by autoclaving 10 minutes at 120 C., and slant.

3. *Blood Agar plus Antibiotics*

Purpose.—Isolation of Blastomyces dermatitidis, Blastomyces brasiliensis, Histoplasma capsulatum.

Composition.—The formula follows.

Brain-heart infusion [1]	37.0 gm.
Agar	20.0 gm.
Distilled water	1,000.0 ml.

Procedure.—Dissolve ingredients in a water bath; place 17 ml. in a 25 by 150 mm. test tube. Autoclave at 120 C. for 10 minutes. Cool to 50 C. and add aseptically

---

[1] Brain-heart infusion is prepared in dehydrated form by several companies.

1.0 ml. of blood, 340 units of penicillin and 680 units of streptomycin per tube, and slant.

4. Brain-Heart Infusion Agar

Purpose.—Isolation of A. bovis (shake tubes).

Composition.—The formula follows.

Brain-heart infusion[1]	37.0 gm.
Agar	15.0 gm.
Distilled water	1,000.0 ml.

Procedure.—Dissolve ingredients in a water bath; place 8 ml. in an 18 by 150 mm. test tube. Sterilize by autoclaving 10 minutes at 120 C. Do not slant. To use, melt agar in a water bath, cool to 50 C., inoculate with a loop, mix thoroughly, allow to solidify, and incubate.

SUMMARY

The accompanying table summarizes the various types and sources of materials that are required by the laboratory for the successful demonstration and isolation of fungi in given types of fungus diseases.

Source of Specimens and Media Required for the Demonstration and Isolation of Fungi from Specific Types of Fungus Diseases

Disease	Type of Specimen	Isolation Medium
Superficial mycoses		
Erythrasma	Skin scrapings	None available at present
Piedra	Clipped hair	Sabouraud's dextrose agar
Tinea nigra	Skin scrapings	Sabouraud's dextrose agar
Tinea versicolor	Skin scrapings	None available at present
Trichomycosis axillaris	*Clipped hair*	None available at present
Cutaneous mycoses		
Candidiasis	(a) Skin scrapings (b) Scrapings from mucocutaneous areas (c) Vaginal scrapings	*Sabouraud's dextrose agar*
Onychomycosis	*Nail scrapings*	Sabouraud's dextrose agar
Tinea capitis	Plucked hair	(a) Sabouraud's dextrose agar (b) Thiamine-dextrose agar
Tinea corporis	*Skin scrapings*	(a) Sabouraud's dextrose agar (b) Thiamine-dextrose agar
Tinea pedis	Skin scrapings	Sabouraud's dextrose agar
Subcutaneous mycoses		
Chromoblastomycosis	(a) Crusts and scrapings from warty outgrowths (b) Exudate from lesions	Sabouraud's dextrose agar
Mycetoma	(a) Pus from draining (b) Aspirated fluids fro (c) Biopsy specimens	(a) Sabouraud's dextrose agar (b) Brain-heart infusion agar for actinomycotic mycetomas (shake tubes)
Rhinosporidiosis	(a) Biopsied nasal and *ocular polyps* (b) Skin	None available at present
Sporotrichosis	(a) Pus 1 (b) Aspir	Sabouraud's dextrose agar
Systemic mycoses		
Actinomycosis	(a) Pus from *draining sinuses* (b) Aspirated fluid from subcutaneous abscesses (c) Sputum (d) Spinal (e) Bronch	Brain-heart infusion agar; shake tubes
Blastomycosis, North American	(a) Scrapings *from edge of skin lesions* (b) Pus from open abscesses (c) Pus from sinus tracts (d) Urine (e) Sputum (f) Bronchial washings	(a) Sabouraud's *dextrose* agar (b) Blood agar plus antibiotics
Blastomycosis, South American	(a) Scrapings from edge of *skin lesions* (b) Scrapings from mucous membranes (c) Biopsied lymph nodes (d) Sputum (e) Bronchial washings	(a) Sabouraud's dextrose agar (b) Blood agar plus antibiotics
Candidiasis	(a) Sputum (b) (c) (d) (e)	Sabouraud's dextrose agar
Coccidioidomycosis	(a) Sputum (b) (c) (d) (e) [illegible] skin lesions (f) Pus from draining abscesses and sinuses	(a) Sabouraud's dextrose agar (b) Blood agar plus antibiotics
Cryptococcosis	(a) Spinal fluid (b) Sputum (c) Pus from abscesses (d) Pus from sinus tracts (e) Scrapings from skin *lesions* (f) Urine	Sabouraud's dextrose agar
Geotrichosis	(a) Sputum (b) Bronchial washings (c) Stools	Sabouraud's dextrose agar
Histoplasmosis	(a) Blood (b) Sternal marrow (c) Sputum (d) (e) (f) (g) Exudate from *ulcers* (h) Scrapings from *skin lesions*	(a) Sabouraud's dextrose agar (b) Blood agar plus antibiotics
Nocardiosis	(a) Sputum (b) Spinal fluid (c) Pus from *abscesses* (d) Bronchial washings	Sabouraud's dextrose agar
Miscellaneous mycoses		
Aspergillosis	(a) Sputum (b) Bronchial washings	Sabouraud's dextrose agar
Mucormycosis	(a) Sputum (b) Bronchial washings (c) Biopsy material	Sabouraud's dextrose agar
Penicilliosis	(a) Sputum (b) Bronchial washings	Sabouraud's dextrose agar

PSYCHIATRIC TECHNIQUES IN MEDICAL PRACTICE

A. Z. Barhash, M.D., New York

Psychiatry, as a medical specialty, today finds itself vastly oversold, in the sense that the public expects of it much more than it will be able to deliver for many years to come. As someone interested in the public health aspects of psychiatry, I want to discuss some of the things we can do to satisfy the psychiatric needs we see and the demands we have created. In the confusion besetting the field of mental health, I have attained at least two clear convictions. The first is that the medical profession will never do a satisfactory job of safeguarding and raising the health level of the population until it is in a position to contribute more effectively to mental and emotional health. The second is that such a contribution will never be made until the major portion of it can be made through the work of nonpsychiatric medical practitioners. Up to now the medical profession has restricted its work largely to the cure and prevention of those ills which are caused by bacteriological and toxic agents, degenerative processes, neoplasms, and other such physical factors. Until it broadens this approach, it will continue to neglect a major source of morbidity—that which results from emotional conflicts and tensions. Up to now this area has been left almost exclusively to psychiatrists, but it is a task which is impossible in its proportions for a small, specialized group. For the job to be done, it must be undertaken by the medical profession as a whole. I think it is nonsense to speak of the hundreds of thousands of psychiatrists who must be trained to take care of the emotional health of our population. The training of such numbers will be impossible to achieve—and economically impossible to maintain if it were achieved. Furthermore, such an overwhelming undertaking is unnecessary. What is necessary, what is possible, and what is altogether practical is that general practitioners and pediatricians, allergists, obstetricians, surgeons, and even roentgenologists, learn something about their patients' emotions and the role that these play in health and illness. Let me make it clear that I am not trying to turn all physicians into psychiatrists, nor am I suggesting that the specialty of psychiatry be abolished. Presumably, there will always be room for specialists who will occupy themselves with the study and treatment of emotional illnesses. However, the vast majority of persons who can be helped to better health through assistance with their emotional problems need not and should not go to psychiatrists. In the course of their ordinary contacts with medical practitioners, they have a right to expect that these physicians will have the wherewithal to assist them with the usual run of emotional ills. Such an expectation is not unreasonable, and if the medical profession applies itself to the task, it will be able to meet it with complete adequacy.

I have no illusions about the perfection or the completeness of today's psychological insights. There is a tremendous amount that even the best informed and most skillful psychiatrist does not know and cannot do. But in spite of these shortcomings psychiatrists do know certain things about mental and emotional development which can be utilized to make people healthier and happier. Furthermore, most of these things we know are of such a nature that they can be learned and effectively utilized by physicians who are not specialists in the field. And let me make it clear that when I speak of using psychological skills I refer to their application—not to the narrow field of severely neurotic patients or the somewhat broader field of patients with so-called "psychosomatic" symptoms—but I mean the utilization of these insights and skills in the case of every patient who enters a physician's office. It has become common knowledge that psychogenic factors play an important role in many more illnesses and with many more patients than was thought conceivable some 10 years ago. At that time, for example, even the best obstetricians thought they had done handsomely by a patient with repeated abortions when they had exhausted all the physical examinations, laboratory tests, roentgenograms and endocrinological studies that might reveal the source of the trouble. Now it is known that beyond what might be uncovered in such examinations, there are instances where a woman's unconscious inability to accept a pregnancy or the role of motherhood may be the real cause of the repeated abortions. Not so long ago the surgeon had done his duty when he repeatedly sewed up, splinted, or put into casts persons who somehow repeatedly got into accidents. Now it is known that an unconscious tendency to punish oneself, and a perverse satisfaction in the resulting suffering, play a large role in the causation of these repeated accidents. But even beyond instances of this kind, even where psychogenic factors play no part in the causation of the illness, it can still be said that every patient who suffers enough to come to a physician has some emotional reaction to his illness. And it is the physician who best understands this reaction who is best equipped to help the patient.

BARBITURATES

Let us have a look at some of the methods commonly employed in the treatment of emotional difficulties. I have not seen the latest figures on the sale of barbiturates, but as I recall those I last saw, it struck me that even in those states where the sale was restricted to patients with physicians' prescriptions, the amount sold was colossal. The only reason sales can reach such proportions is that the symptoms controlled by barbiturates appear so often among the patients you treat.

Among those for whom barbiturates are prescribed is first the patient with insomnia. The one who is tired all day and restless all night almost inevitably comes away from his physician with some barbiturate. The physician knows that the treatment is only symptomatic, but he has done whatever he could to rule out organic pathology, and beyond that he feels that there is nothing left for him to do but to make his patient comfortable. Since most of

---

Read before the Yale Clinical Congress, New Haven, Conn., Sept. 13, 1950.

these conditions are chronic—and I refer here particularly to the chronic ones—the physician who prescribes barbiturates to such a patient has started him on a long term program of taking this medication, which as even the labels on bottles indicate, "may be habit-forming." I leave it to others to point out the possible pharmacological effects of continued use of barbiturates. What I am better acquainted with are the clinical effects, and these are such as to give conscientious physicians cause for concern about the widespread use of these drugs. The course is so regular that it can generally be charted in advance. The patient takes the prescribed dose and gets relief. Several weeks later the effectiveness of the original dose has worn off, and he is getting no more sleep with it than he was getting before starting medication. Either on the suggestion of the physician, or without asking for such advice, he keeps increasing the dose, always with the result that the increased dose at first brings relief, only to have it wear off in a shorter or longer period of time. At last he ends up taking as much of the drug as he dares, or as much as his physician will allow him, or as much as he can take without feeling drowsy all the next day. What has happened to his sleep in the meantime? He still sleeps just about as little as he slept before he started taking barbiturates. Then he decides to go to another physician who again puts him through all the clinical tests, which again reveal no organic etiology. When that is over, the patient begins a new course with a different sedative. But he's only on a merry-go-round, —always on the way back to where he started from, and getting very dizzy in the process.

There is one other group of patients treated to a steady diet of barbiturates. They are the ones with persistent anxiety symptoms, either appearing by themselves, or accompanying somatic disorders. They are the patients who are restless, who complain of jitters and cannot relax. They perspire easily, get flushed, have a rapid heartbeat, and maintain a constant attitude of tension. They are the ones who are suspected of hyperthyroidism without having it, the ones who have innumerable gastrointestinal series, without any pathology ever being discovered. They too respond well to barbiturate medication in the early stages, but a steady diet of these drugs results as badly for them as it does for the insomniac, the only difference being that the ill-effects here show a somewhat greater variability. It is evident then that even in the control of superficial symptomatology, continuous use of barbiturates can hardly be justified. If one looks just a little deeper, there is even less excuse for their being used as extensively as they are. The same reasoning applies here as applies to the use of potent analgesics and opiates for the control of pain. Easy resort to these drugs makes physicians too casual and too negligent in their efforts at discovering and correcting the basic pathology. It is known well enough that the premature use of morphine can lead to the neglect and further development of an otherwise-correctible surgical condition. In like manner it behooves the medical practitioner to wonder what it is he is shielding, what he is allowing to develop further, when he starts dosing his patient with barbiturates, which have only the effect of enabling the patient to tolerate a condition which otherwise might be corrected. The patient with an anxiety state who is repeatedly dosed with barbiturates is not being relieved of his anxiety. The outward manifestations are being covered, while the basic tension mounts up, while the etiological factors continue to grow, and while new symptoms develop which will be more damaging and harder to treat. There are, of course, instances in which even the continued use of opiates is justified, those in which the condition is hopeless, and physicians wish to make the patients as comfortable as possible. But we must make sure *before* we resort to this kind of medication that the condition is really hopeless. That, precisely, is what the medical profession has not done in those emotional ills in which sedatives are overused. Not only are many of these conditions less hopeless than they have been considered, but the well-informed and conscientious physician today can treat many of them in his own office, without resort to help by specialists, and without barbiturates.

I do not want to leave the impression that in my opinion there is no legitimate place for the use of barbiturates. There are many instances where the impact of an acute crisis can be materially lessened if the patient's reactivity is diminished by the use of sedatives. There are others in which the artificial induction of several nights' sleep can be of tremendous help in withstanding a physical illness, in living through a crisis, or in gathering strength for the solution of some difficult problem. There is a group of convulsive disorders in which the thoughtful and prolonged use of sedation constitutes the major therapy. But aside from these conditions, the continued use of sedation is something which on its face is suspect, and in the vast majority of instances is bad medicine.

REST CURES

Among the substitutes for sympathetic understanding and effective treatment of emotional ills, one that holds a high priority in today's medical practice is the prescription of rest cures and vacations. Here again I do not want to be too sweeping in my dismissal of such treatment. There are some patients suffering from fatigue in whom a rest and a change can have beneficial results. Clinical observation convinces me, however, that only a very small proportion of patients so treated fall into this group. In too many instances the physician recommends a rest or a vacation because he does not know what else to do, or perhaps because he is projecting his own feeling that he himself could benefit by a rest. The patient with chronic fatigue, who suffers not from overwork but from the ravages of inner conflicts, takes these conflicts with him when he goes on vacation, and he will continue to be as fatigued during and after the vacation as he was before. The patient who suffers the effects of an impossible situation, impossible because of its intrinsic nature or because of his own inability to adjust to it, is going to come back from the vacation to find himself in exactly the same spot he was in before, and his symptoms (whatever they were) will quickly reappear, even if he has benefited temporarily from the vacation. The prescription is worst of all for patients who come to the physician with feelings of helplessness, hopelessness, inadequacy, and frustration. Often such patients are told to get away from it all, to go somewhere where they can have a good time and get a rest. These are the patients who jump out of hotel windows or die from an overdose of sleeping pills taken while away from home. They are the ones whose inner fears cause them to go to a physician looking for support, and instead they are sent off to a strange environment where there is no one to lend them that support. They are often persons in the throes of an early depression, in whom close watch and rapid treatment can make the difference between life and death. But they are sent off to a place where no one sees them, where they are left altogether to their own resources, and where medical help is not quickly available. Even when the ill-effects of a vacation are less traumatic and less drastic, the obligation "to have a good time" when one is not in the mood for it can often be more oppressive and more laborious than going on with one's daily responsibilities.

ELECTROSHOCK

Lest it be thought that as a psychiatrist I take a holier-than-thou attitude toward the rest of the profession without seeing the weaknesses in his own specialty, I should like to point out our own indiscriminate use of some therapeutic techniques. As a matter of fact, we psychiatrists have contributed in no little measure to the misuse of both barbiturates and rest cures. Perhaps we have come along a little in these respects, but there are still enough of us who use these treatments thoughtlessly. However, our major sin of the moment lies in our misuse and overuse of electroshock therapy. It is a form of treatment that is specifically suited to certain conditions, and when restricted to those conditions can be dramatically and lastingly effective. However, the dramatic quality of this treatment, its ease of application, and the fact that it is not time-consuming (and therefore is very profitable)—all contribute toward making it one that is easily abused. There are recurring controversies within psychiatric groups, not so much over the effectiveness of the treatment, but over its legitimate field of application. I am among those who feel that many psychiatrists resort to electroshock treatment too quickly, too frequently, and too exclusively. It is very useful in severe depressions, especially where the threat of suicide makes quick treatment imperative, or where other forms of treatment such as psychotherapy have already proved ineffective. Nonpsychiatric medical practitioners cannot sit as judges in this controversy, but I would advise that in those instances in which one has occasion to refer patients for specialized psychiatric treatment one be cautious about referring them to psychiatrists who make too facile or too general use of this form of treatment.

ACCUSATION AND CONFRONTATION

One "psychiatric technique" too frequently employed is that of accusation and confrontation. Perhaps it is surprising that I list these among frequently used devices in medical practice. I am sure that very few physicians in their own minds place this label on what they do to their patients. But a critical look reveals that the physician who uses this method is no rarity. A patient presents himself to a physician with troublesome and sometimes baffling complaints. The physician investigates the case conscientiously and treats the patient with devotion and care. Then it turns out that the patient's illness is without organic basis, and at this point the physician feels cheated and put upon. He confronts the patient accusingly with a stack of normal roentgenograms and laboratory reports. He tells him there is nothing wrong with him, that he is only imagining his symptoms, that he is a neurotic, and sometimes even that he is a faker. The manner in which this confrontation is carried out varies anywhere from subtle diplomacy to brusque brutality. But even in the former instances the patient understands its meaning oftener than the physician gives him credit for. The patient feels perplexed and resentful about an unfair accusation. It is not his fault that the laboratory tests were normal, and he knows full well that his symptoms are real, that they are not being imagined and certainly not being faked. If he has it on the authority of the physician that such symptoms must be accompanied by positive objective findings, the only conclusion he can draw is that the physician was not skillful enough to locate the pathology, and there is nothing for him to do but go to another physician and subject himself to another series of investigations. On the other hand, a physician who appreciates the potency of psychogenic forces in the causation of somatic symptoms, one who has a sympathetic understanding of the state of mind of the sick and frightened patient, is able to be of tremendous help to his patient and to come off with much more credit to himself. The same set of negative findings can be presented to the patient as something reassuring rather than as a proof of his dishonesty. They can be presented as something perfectly understandable, rather than as something that is baffling and mysterious. The reassurance, accompanied by the physician's understanding of the patient as well as the laboratory reports, can in itself be tremendously helpful. Beyond that, it clears the decks for a consideration of what might be involved when organic pathology was not present.

UNINFORMED PATIENTS

Among those medical practices which must be termed psychologically unsound, one of the most frequent is that of keeping the patient ignorant of the facts of his illness. One result of this practice has been decried by many physicians. It is the habit the American public has developed of seeking medical information from a variety of lay sources, mostly in newspapers and magazines, in which the authors are more interested in the salability of the printed matter than in its salutory effect on the health of the patient. The stirring up of confusions, the whipping up of anxiety, and the mass stampeding to the use of untried drugs are only a few of the undesirable effects. But those in the medical profession who criticize writers for catering to the curiosity of the public should stop first to examine their own role in having created this curiosity. Considering its educational level, the American public is shockingly ignorant about the human body, its anatomy and physiology, its health and its illness. Some portion of the fault for this ignorance rests with the nation's educational institutions, which have convinced themselves that it is more important for a person to know the third declension in Latin than it is for him to know what the stomach is, where it lies, how it works, and what disturbs its workings. But we physicians also carry a large share of the blame. It is everyday practice for physicians to give vague, noncommittal names to the conditions for which they treat their patients and to give treatments without identifying or explaining them. In no other country are patients of equal sophistication and equal educational level treated with so little respect for their curiosity and their understanding. I know of no country in western Europe in which an intelligent and well-read patient will report that he has received a course of injections from his physician, without being able to identify the condition for which he was being treated and the material that was being injected. But that is an everyday experience in this country. It is as though the medical profession had reached the tacit agreement that "the less said the better." From the point of view of one interested in mental health, it must be said that this conspiracy of silence has a most unfortunate effect on the general health level. It creates an atmosphere of mystery and confusion in which the patient is blindly buffeted between fear of the unknown and hope for magic. This cloak of silence with which we physicians surround ourselves has made patients anxious about themselves and distrustful of us. It is little wonder that they gobble up every bit of information which comes their way that might reveal to them some secret which physicians have been trying to hide. All this is the more unfortunate because it is so very unnecessary. The average American physician is so well-trained and so well-informed that he need not be at all ashamed of sharing with his patients his findings, his thinking, and his planning. Such openness with the patient will give the physician a more secure position of trust and respect. What is even more important, it will relieve the patient of that sense of anxiety which all persons feel when they are kept in the dark.

TONSILLECTOMIES IN CHILDREN

The failure of physicians to instruct their patients has been especially pernicious in the performance of tonsillectomies in children, a surgical procedure which is carried out on a very large proportion of the population at an age when the patient is particularly impressionable. Since physicians generally do not share much information with their patients, it is hardly surprising that they share even less with children. They assume that children would not understand anyway, and if they did understand, the information would only make them less tractable. Furthermore, they know that the operation involves very little surgical risk, that the patient is bound to come out without any serious damage. Therefore, they see little reason for arousing his anxiety by discussing the details of the coming operation. Those who measure damage from tonsillectomies in terms of anesthetic deaths or fatal hemorrhage are perfectly right in saying that in competent hands the surgical risk is a minimal one. However, if one considers the damage that tonsillectomies have inflicted on people by traumatizing them emotionally and causing them future states of tension and unhappiness, by making them feel less whole and less able to care for themselves in a hostile world, and by making them less able to derive full benefit from the ministrations of the physician, then one must say that the tonsillectomy looms as a very serious operation. Should the tonsillectomy as an operation be abandoned then? For my part, I should not like to take that responsibility on myself so long as more competent authorities feel that it is advisable to remove the tonsils either as a source of infection or as a mechanical impediment. I say only that if physicians are going to keep on taking out tonsils in the numbers that they have, they ought to be a little more cognizant of what happens to the patient, and much more effective than they have been in the past in minimizing the trauma. To the physician, the tonsillectomy is nothing more than a minor operation in which the two most frequent annoyances are an occasional bleeder or a loudly screaming child.

What is it like to the child himself, i. e., the child who is completely unprepared or who in place of preparation has received some evasion or some lie ("You're going to get an injection." "We're just going for a ride." "The doctor's just going to look at you.")? First of all, the child is taken out of the house hungry and brought to a strange and somewhat fearsome place. Even the adult reacts with apprehension and with a greater readiness for panic when he is hungry. (This is evidenced by our experience in the last war when the badly fed battalion was the one with the greatest number of psychiatric casualties and the one least able to accomplish its combat mission. On the other hand, those groups in which the commanding officers paid special attention to the maintenance of a good hot food supply were able to withstand surprising pressures.) This hungry and therefore apprehensive child is often kept waiting for long periods of time, and he sees and hears things which tend to increase his apprehension. He is then separated from his mother, usually not by his own physician, but by a strange and sometimes masked attendant or nurse. He sees other masked and robed figures, he smells strange smells, is given a painful injection, has a mask put over his mouth and nose, and is forced to breathe something which chokes him. Is it too surprising that to the uninitiated child the most frequent conclusion is that he is being killed, and that all the strange doings are nothing more than an accompanying ritual? He awakens feeling ill and experiencing a soreness in his throat, which convinces him that the attempt on his life somehow involved a stab in the throat. At this point he is usually still among strangers, and it is only when he is fully recovered from the anesthesia that his mother is allowed to see him. By that time he realizes that he has escaped death, but the anxiety which accompanies the miraculous escape stays with him, as do the confusion over why he was subjected to it, and the resentment against those who did it. Does all of this sound very fantastic? These are not my own fantasies. These are experiences recalled by many children soon after the tonsillectomy, and by many more adults in psychiatric treatment recalling traumatic experiences of childhood. So many psychiatrists have obtained such strikingly similar material from so many patients that there can be no doubt about the validity of these reports.

I have said before that I do not expect the medical profession to give up tonsillectomies. I do not expect every child who is going to undergo one to be sent first for a course of treatment by a psychiatrist. Any pediatrician, any general practitioner, any ear, nose, and throat specialist who takes the trouble to think about how a tonsillectomy might affect the child will readily find means to avoid the worst of the possible damage. I stress this example not only because the tonsillectomy is such a frequent procedure, but more because a consideration of what the physician might do for the tonsillectomy patient suggests much of what he can do by way of emotional assistance to patients in other circumstances. This, then, is what the physician might do for a child facing a tonsillectomy:

As a first requirement, I would say that he ought to be honest with the child, and as a corollary to the honesty, he ought to be informative rather than secretive. Depending on the age and the level of understanding of the child, the physician should tell him what is wrong, what the anatomical facts are, what is going to be removed, how it is going to be removed, and what the effects are. I know that when I use the phrase "depending on the level of understanding," many physicians will use this as an escape, because they assume blandly that children understand nothing and, therefore, they need explain nothing. Those of us who work with children realize that they understand much more of the important things than we ever give them credit for. What they fail to understand are not facts and ideas, but rather our complex and garbled terminology. Therefore, it behooves the physician who is not being understood to find simpler and more understandable ways of communicating his information, rather than assuming that the child cannot possibly grasp it. Beyond being honest and informative, the physician should be able to anticipate the major sources of the patient's anxiety. One of these is the aspect of strangeness which accompanies anyone's first surgical experience. If possible, the patient should be introduced to the scene before the actual operation. When he is taken from his mother, it should be by the physician or by a nurse with whom he is acquainted rather than by a total stranger. Even when it is not possible to make him familiar with the operating room in advance, it is at least possible to let him handle and smell an ether mask or, better yet, to let him take it home for a few days, where he can get familiar with it by putting it on himself, on other children, or on dolls. The mother should be with the child to the point where he is anesthetized and immediately on awakening. Even if it may be somewhat of a nuisance to have an anxious mother around, it still serves an important purpose in protecting the child. Although it cannot be avoided that the child be brought to the operation in a hungry state, a more careful attention to scheduling would eliminate the need for his sitting around hungry for many hours while awaiting his turn. By way of anticipating sources of anxiety, the physician should know that the mouth, as one of the early, primary sources of physical gratification, is emotionally very important to the child. The information about what is to be done should be so transmitted as to reassure the child about any possible damage to this primary source of gratification. Also by way of anticipating anxieties, the physician should know that some children will look on the surgical procedure as a punishment for crimes they imagine themselves to have committed (aggressive thoughts, or wishes). Here again, a reassuring, honest attitude will help eliminate such misinterpretations. Above all, the physician should avoid anything that can encourage fear and confusion—as happens in enuretic children, for example, when they are told that the tonsillectomy is going to cure the enuresis. Since they inevitably carry a load of guilt about their enuresis, they look on the operation not as a cure but as a punishment, an attack which will be repeated if the enuresis continues. For many such children, the tonsillectomy becomes a substitute castration.

SUMMARY AND CONCLUSIONS

As I mention ways in which physicians can be helpful with the emotional aspects of their patients' health, it may seem that I am not writing about psychiatric techniques, but rather about common sense, fundamental decency, sensitivity and intuition. Actually, that is all I am writing about, but intuition, decency, and common sense can be vastly more effective when combined with adequate knowledge about the emotional growth, development, and functioning of the human being. The good physician has always been honest with his patients; his honesty can be more meaningfully applied when he knows what security the patient seeks from it and the effect that it can have on the patient's well-being. The physician today must know a great deal about the emotional needs of his patients. He should know the possible consequences when these needs are not satisfied, for without such knowledge he cannot understand many of his patients' illnesses. He should know that when a patient comes to him whom he cannot help with medication and surgery, he may still be able to help him with reassurance, support, sympathetic understanding, and a clearing up of frightening misconceptions. He should know that a competent and sympathetic physician fulfills an urgent need for many patients as a parent-substitute, who serves as the guardian against both physical dangers and emotional terrors threatening their health. When common sense, sensitivity, honesty, and intuition are bolstered by this kind of psychological knowledge, then one can speak of the result as psychiatric techniques. But these are techniques that are available not only to the psychiatric specialist. They are equally available to the nonpsychiatric medical practitioner. The health needs of the population demand that they be adopted as everyday techniques by everyone practicing medicine.

National Association for Mental Health, Inc., 1790 Broadway, New York, N. Y.

Leiomyomas of Stomach.—Leiomyomas of the stomach which are large enough to cause clinical symptoms are not rare and will be encountered occasionally in roentgen studies. Such tumors often give evidence of their presence by gastric bleeding. Unless they produce obstruction, they cause little digestive distress and no cachexia, and often may be found when exploratory operation is done for other conditions. Because many of these tumors of smooth muscle origin may be sarcomatous, they should be removed by resection of the stomach rather than by local excision. If removed cleanly leiomyomas do not recur.—Samuel F. Marshall, M.D., and William A. Meissner, M.D., Leiomyoma of the Stomach, *The Surgical Clinics of North America,* June, 1951.

REFERRING YOUR PATIENT TO A PSYCHIATRIST

John M. Flumerfelt, M.D., Cleveland

A psychiatrist at a medical meeting of this kind would have been unheard of not too many years ago. If he had been present, he would probably have talked about insanity, illustrating his talk with microscopic pictures of brain damage.

Today I am not going to discuss the broader path created by psychiatry since then, nor its increased acceptance as an important functional part of the practice of medicine. The changed status of psychiatriy is abundantly evidenced by the fact that today I am going to consider the problem of referring an adult neurotic person to a psychiatrist—a person who is sane, sensitive, likely to have fears and prejudices related to psychiatry, likely to take offense or even to become alarmed at this suggestion from his physician.

In the last 50 years people have been given an idea that is perturbing and hard to believe: they have been told that man does not know all of his own mind; that many of his thoughts and actions, as well as many of the symptoms he may have, are motivated by psychic forces within himself of which he is unaware. The problem was simpler four centuries ago, when the strange behavior of the mind was thought to be caused by demons who supposedly had taken up residence in the unfortunate sufferer, or half a century ago, when much more scientific beliefs held that each departure from the "normal" was caused by a physical disease process which would reveal itself in an organic pathology if only that could be found. For these and other reasons, the neurotic patient is not likely to take kindly to the suggestion that his troubles are due to unconscious forces acting on his thoughts and emotions; and the physician who is considering referring his patient to a psychiatrist may well be pardoned a modicum of hesitancy or even skepticism. For one thing, would it not be asking a great deal of both physician and patient to ask them to accept such a hypothesis as true just because a small number of people say it is? And for another thing, would it not be natural for them to suspect that such a notion might lend itself to charlatanism and exploitation of unethical, unscientific, or otherwise disreputable varieties? That strange ideas might be put into a person's mind?

To these general objections, which may well form the backbone of resistance to a psychiatric referral, I may add others that are individual.

Persons who are well-informed on other matters may still consider referral to a psychiatrist as evidence of "queerness" or even insanity. Twenty or 30 years ago this was almost literally true.

Or, the patient may attach to the word "neurosis" the connotation that if indeed he is neurotic and if his neurosis is found out, he will be set apart from his fellow men as a weakling, one who lacks will power, and a supine seeker after sympathy at the expense of others.

In addition, there are always less conscious objections on the part of the patient, which are not likely to become apparent until after a psychiatric study has been started. By and large, these objections are made up of feelings of guilt that pertain to equally unconscious and forbidden impulses, and the patient, without knowing why, may feel exceedingly anxious about any probing into his inner self. Although both the patient and the referring physician may not have access to this category of objection, it is inevitably present and can be silently acknowledged by the physician.

Even in the case of patients who are willing and even eager for psychiatric referral, one can be almost certain that some of the objections so far mentioned will be present and will continue to require attention after treatment has been started. The psychiatrist, like his medical colleague, appreciates a clear field for treatment, and any help given by the referring physician which removes even some of the more superficial obstructions makes the referral that much better for the patient as well as for the psychiatrist's efforts.

Another and valid difficulty in the way of referral is that psychiatric treatment of neurosis may take a long time and therefore be very expensive for the patient. So far, there is no happy answer to this objection, in spite of the fact that psychiatrists, like other medical men, devote much of their time gratis to persons who cannot pay for treatment, in spite of social efforts such as those made by the Community Chest, and in spite of generous private assistance such as those in Cleveland have been fortunate to receive. However, it is a fact that psychiatric patients, just because they are human, are likely to work harder to get well if with their own efforts they are able to help pay for treatment. I do not mean to imply for a moment that every patient will become a malingerer if given half a chance. I do mean that the great majority of grown-ups are adult enough to feel better about accepting treatment and to make better use of it if they can pay for it themselves. Therefore, in psychiatry, just as in all medicine, there is the universal and paradoxical problem that has yet to be solved: how to provide necessary medical care without lessening the self-respect of the patient or, at the same time, his respect for the help given him.

With a bona fide neurosis a brief therapy usually carries with it a limitation on the degree of cure effected, despite the continuing efforts of psychiatrists to bring about some solution of the problem. Sometimes, however, a great deal of relief from symptoms may result from only brief treatment, and in certain cases it is wise not to carry treatment further. The point is that the length of time required for psychiatric treatment varies and hence treatment may not always be so expensive as the patient at first fears. Whether the treatment is to take a long or a short time can best be determined by the psychiatrist after he has seen the patients and has had an opportunity to form an opinion.

Read before the Fourth Clinical Session of the American Medical Association, Cleveland, Dec. 6, 1950.

There is a good reason why psychiatric treatment with some patients takes a long time. A neurosis existing in a person's mind may be likened to an extensive mass of scar tissue that hampers the functions of a physical part. Scar tissue, as you know, is rigid and inelastic. It has a tendency to constrict and, in so doing, creates greater dysfunction the older it becomes. Any efforts to eradicate the scar and to check its hindrance of healthy functions are time-consuming and repetitious. Sometimes the physician must settle for a partial improvement. In other cases, with great persistence on his part and the determined cooperation of his patient, he can win through to a full return of function.

In spite of the desire to shorten the time required for psychiatric treatment, there is no push button armamentarium at the disposal of the psychiatrist to enable him to go at once to the center of the problem and to dissolve it. The way is blocked by mental defenses that may take months or even years for the most skilled in treatment to surmount, and any method that by-passes these defenses cannot achieve a cure in the full meaning of the word, even if important symptomatic relief is obtained.

Considering all of the objections mentioned so far, the fact that most patients will accept their physician's recommendation and go to a psychiatrist is in large measure a tribute to their confidence in the physician and to his reasonable explanation of their need for this kind of help. There are some patients, of course, whose wish for psychiatric help is already considerable and whose knowledge and sophistication with regard to such help has brought them past their objections. These patients do not present a problem for referral and need not be further considered in this discussion.

However, many patients need some help from the referring physician. In assessing the problem, the physician should consider, first of all, how much the patient wants relief from his symptoms. Are they painfully distressing to the patient, as, for instance, severe anxiety and phobic symptoms are painful in themselves? Or, does the patient really feel that his functioning in life is so severely handicapped that he urgently desires assistance and will work hard to get well? Or, at least do his family and friends find his present state so intolerable that they put firm and consistent pressure on him to seek treatment? The more the patient's and his friends' attitudes toward his symptoms fulfill these criteria, the better is his chance of accepting a psychiatric referral and of being helped once he has begun treatment.

The referring physician, of course, is very familiar with such criteria because he knows that a patient who suffers pain, or whose functioning is impaired by any illness, already is provided with a motive to seek medical care—a motive far more effective in securing cooperation in treatment than any amount of persuasion or coercion from other sources.

The point of this is—and it may often be overlooked by the referring physician—that the same motivations, generally, are necessary for a successful psychiatric referral and successful treatment. Recently a patient of mine who had been in treatment for several years refreshed all of this for me by volunteering, "If I hadn't been desperate to get free of my condition, I'd never have gone through with this treatment and told you the few things about myself that I knew at the beginning and most that I didn't know until later." It was also true that before starting psychiatric treatment, she had tried many other "cures," including a major operation and an imposing list of medicinal preparations. Her symptoms had made her their prisoner from the time she was 14 years old until after she started treatment at 40 years of age.

My patient's comment, by the way, helps to dispose of two other objections popularly held by people: (1) that psychiatric treatment is a pleasurable recreation for wealthy and indolent women, and (2) that just talking about one's self cannot amount to anything.

If the criteria described are not met by the patient and his family, if he can deny or otherwise elude his anxieties, or if he has someone at home who helps him to escape from facing the facts of his illness, the chances for a successful psychiatric referral are slim. If, in addition, the referring physician or the psychiatrist, after repeated attempts, cannot convince him of the realty of his illness and by that approach produce in him a healthy anxiety to be treated, the chances of a successful outcome are remote.

However, it is possible for the physician to increase his patient's objections to a psychiatric referral. If the physician is apologetic; if he says to the patient, "Now, I've examined you thoroughly and find nothing wrong and I think you'd better see a psychiatrist"; if he says or implies, "There's nothing to it; it's all in your head"; if he reveals by word or act that he is cross and out of patience—then the patient will surely feel that his difficulties are abased and that he is being "kicked out." His reaction will be one of resentment, with a proportionate decline in his chances of being helped.

Finally, the physician, however much he may want to avoid arousing the patient's prejudices, should always tell him that the doctor to whom he is being referred is a psychiatrist. Otherwise the patient will feel deceived and his confidence in the new treatment may be destroyed. The psychiatrist himself cannot carry on such a hoax, and for at least one very good reason: if he expects the patient to be honest with him, he must be no less honest with the patient.

In preparing the patient for psychiatric referral, the physician should, first of all, do what he would naturally do—take a history and make an adequate physical examination. If these point to a psychological disturbance, he can ask the patient to tell more about himself, explaining to the patient that the symptoms from which he suffers suggest there may be things in his life which are bothering him. It is better to avoid the leading question. For instance, instead of asking directly, "Is your marriage a happy one?" the physician might say, "Can you tell me a little more about your marriage?" In this way the physician can imply that what has been told so far is not enough to explain the symptoms, thereby putting a firm but gentle pressure on the patient to reveal more and more until the general nature, at least, of the problem is clear enough to be understood.

However, an otherwise astute physician will sometimes make the mistake of taking too quick an approach to a touchy problem which is obvious to him but not to the patient. If the first question has revealed a serious marital problem, the best tactic is to ask the patient casually whether he thinks there might be a difficulty of this kind. The physician should accept a quick and vigorous denial instead of immediately confronting the patient with all the evidence contrary to the patient's opinion. Unless the physician desists for the time being at this point, he may so alarm the patient that later efforts by himself (or by the psychiatrist) may be of no avail. Subsequetly the physician may return to the topic and find the patient ready to admit the problem, the bond of confidence presumably having grown stronger.

If subsequent attempts fail, however, the physician may elect to show the patient by way of everyday examples, and without touching on the serious problem observed, how emotions can produce changes in the body's functions. The purpose of such an approach is to give the patient some intellectual conviction about his need for psychiatric treatment, and it may succeed at least to the point where the patient is willing to "try out" a psychiatrist. Indeed, a "try-it-and-see" approach often makes it easier for the patient to get under way.

Sooner or later the patient will interpose some of the objections I have been considering, and his physician should encourage him to tell exactly how he feels about going to a psychiatrist so that factual explanations may be offered in an attempt to undo fear and prejudice. A discussion of this kind may need to be repeated more than once, and the physician should not relinquish his goal of referral simply because the first time he broaches the subject to the patient, he meets with a tenuous or even a flat rejection. Time, patience, and reasonable persistence will eventually succeed with many patients, whose distressing symptoms will also influence them to seek relief.

There are some patients, however, who are so afraid of psychiatry or so prejudiced against it that referral becomes impossible. Whether a patient will eventually accept psychiatric referral can be determined only after reasonable efforts have been made to persuade him. It is better for the physician to desist than to threaten the patient or to force him to go to a psychiatrist against his will—an imposition resented by any adult and one that inevitably boomerangs against successful treatment.

Whether the patient eventually accepts psychiatric referral or not, the physician should be firm about maintaining the need for this kind of help from the time he first recommends that the patient see a psychiatrist until efforts at referral have either succeeded or failed. If, instead, the physician goes against his better judgment and gives in to the patient's demands for further studies or other kinds of therapy, his position is so weakened by the patient's knowledge of his wavering attitude that failure will probably result. The physician is aware, often enough, of the patient's desire to have a physical instead of an emotional cause for his symptoms. Moreover, it is understandable that the physician, not wanting to anger or to alarm his patient, may be tempted to follow a course that avoids the issue; but such a policy is inevitably a shortsighted one. If the physician gives in to the patient and repeats physical measures, even though he does so against his better judgment, he may incur the responsibility of helping to "fix" the patient's neurosis so that psychiatric treatment becomes more difficult or even impossible.

Sometimes the physician may reason that if the patient refuses psychiatric referral and that if he (the physician) does not "do something," the patient may resort to quacks and nostrums, which could do more harm than good. Such an argument has, of course, a realistic side. The physician may rightly point out that a policy of expediency is under his control and that he will at least avoid doing things that are harmful to the patient. However, in deciding upon such a policy, he should take into account the risks already mentioned, plus the fact that most patients who are made obdurate by their fears or prejudices are likely to be unreasonable and difficult to manage in other respects. All too often the physician comes to regret such a policy as he finds himself tiring of the never-ending demands made on him by the patient or hoping that the patient will stay away for a while or perhaps stop coming altogether. Physicians who have had this experience are likely to say, "I don't see how you fellows stand it; it would drive me crazy to be a psychiatrist." Patients are quick to sense their physician's attitude toward them, and when they sense that it is an adverse one, they may more or less consciously punish the physician by increasing their demands on him or by going to someone else. Because the patient is not qualified to assess professional skill, the next person whom he consults may be someone unfamiliar with medical ethics.

In conclusion, it is apparent that this discussion has not touched on the problem of what the physician can do himself in the way of psychotherapy when no psychiatrist or psychiatric clinic is available, or when other circumstances make a psychiatric referral impossible. That is a topic about which much has been written and taught that is good—and much, too, that is sometimes confusing. However, the fact is that psychotherapy has already started when a patient comes to his physician for help, and when the physician has decided that a psychiatric referral is indicated and so advises him.

University Hospitals.

Background of U. S. Scientists.—A statistical analysis that took some five years produced several significant surprises. . . . The first surprise is that small liberal arts colleges are far and away the most productive sources of future scientists among U. S. institutions. Of the 50 leading institutions in this respect (i. e., those that turn out the largest proportion of graduates who become scientists), 39 are small liberal arts colleges. Only three large universities appear on this list of leaders, and only two technological institutions; the others among the 50 are three state agricultural schools and three small universities that lean toward technology. . . . The second striking fact, which may surprise some, is that the institutions which lead in the production of scientists are mainly concentrated in the Middle West. That this region is particularly productive of scientists is confirmed by a study of all the 500 institutions for which indexes were computed. In that ranking the Middle West and the Pacific coast lead the nation, with the Middle Atlantic States and New England next and the South last. . . . In the production of graduates entering some other professions, such as the law, the ranking is quite different. According to a survey made before World War II, the U. S. Northeast is the region most productive of future lawyers.—H. B. Goodrich, R. H. Knapp, and G. A. W. Boehm, the Origins of U. S. Scientists, *Scientific American,* July, 1951.

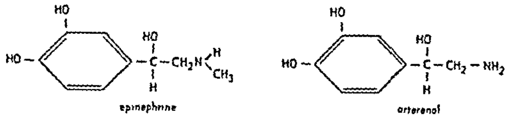
CLINICAL NOTES

TREATMENT OF SHOCK WITH ARTERENOL

Norton M. Luger, M.D.
Allen Kleiman, M.D.
and
Rudolph E. Fremont, M.D., Staten Island, N. Y.

The recent advances in the understanding of the mechanism of shock and its treatment have improved the prognosis of patients in this condition. Nevertheless, the treatment leaves much to be desired. Recent contributions to the study of irreversible shock, as well as clinical experience, have demonstrated that currently available therapy (i. e., various forms of fluid replacement) may be fruitless in advanced or prolonged shock.

The investigations by Goldenberg and his associates [1] of the action of arterenol (nor-epinephrine) demonstrated that this compound increased the blood pressure very markedly by increasing peripheral resistance, without the other effects of epinephrine. Arterenol is related to epinephrine as indicated in the structural formulas. It was thought, therefore, that it might be of some value in the treatment of shock.



Structural formulas of epinephrine and arterenol.

We have recently had the opportunity to observe the action of arterenol in a patient in profound, prolonged shock from a perforated gastric ulcer. The results were sufficiently dramatic to warrant their being reported.

REPORT OF A CASE

A 73 year old white man was admitted to the hospital on Feb. 9, 1950, complaining of indefinite midepigastric pain. According to his history, substernal burning associated with retching had developed four days prior to admission; this gradually disappeared and 24 hours before admission was replaced by a sharp midepigastric pain, which persisted until the patient was admitted to the hospital. Past history was essentially negative for gastrointestinal or cardiovascular symptoms.

Physical examination revealed an elderly white man without obtainable pulse or blood pressure, whose skin was cold, clammy and cyanotic. The lung fields were clear. The heart sounds were poorly audible. The abdomen was distended and tympanitic and apparently contained fluid. There was no spasm, nor was there any audible peristalsis. Roentgenograms of the abdomen revealed intraperitoneal air and fluid. The results of blood studies revealed 14,800 white blood cells, with 80 per cent neutrophils (8 per cent band forms), 6,100,000 red blood cells and a hematocrit value of 58%. The electrocardiogram was interpreted as disclosing only sinus tachycardia and frequent ventricular extrasystoles.

Therapy utilizing nasal oxygen, 500 cc. of whole blood, 500 cc. of plasma, 1,000 cc. of 5 per cent dextrose in saline and 250 cc. of 5 per cent dextrose in distilled water was instituted, but after three hours the pulse rate and blood pressure were still not obtainable and the patient's condition had not noticeably improved.

An infusion of arterenol (2 mg. per liter) was begun at the rate of 100 drops a minute, and two minutes later the patient's pulse was strong and his blood pressure, obtained for the first time, was 140/90. It reached 170/110 seven minutes after the start of the infusion, at which time the patient complained of a headache. The infusion was then slowed to 35 drops a minute, and the blood pressure dropped to 130/80, with relief of the headache. It was maintained at this level by variation of the rate of inflow according to the change in blood pressure.

The patient was observed for an additional four hours, during which time his general condition improved so that laparotomy became possible. A perforation found on the anterior surface of the lesser curvature of the stomach was closed. Two thousand cubic centimeters of yellow serous material (culture of which yielded Streptococcus viridans) and a large amount of air was evacuated from the peritoneal cavity. During the operative procedure the patient received an additional 500 cc. of whole blood, 500 cc. of plasma and 1,000 cc. of 5 per cent dextrose in saline. The use of the arterenol solution, which was administered throughout the operation, was discontinued at the completion of the operative procedure. The patient's blood pressure promptly fell and remained unobtainable for seven minutes, with the pulse becoming weaker. Resuming the arterenol infusion caused a prompt rise of the blood pressure. Four hours postoperatively, with arterenol still being infused at the rate of 30 drops a minute, the blood pressure was 122/78 and the skin was warm. Ten hours postoperatively the infusion was stopped, and again the blood pressure fell abruptly and became unobtainable, but on reinstitution of therapy with arterenol infusion it rose promptly to measurable levels. The infusion was continued at about the same rate for a period of 32 hours postoperatively (38 hours after institution of therapy) and was then discontinued. The patient's blood pressure fell from 138/90 to 90/60 within three to four minutes, and his skin became somewhat cool and moist. The blood pressure stabilized at this level, then gradually rose to 110/70 within an hour and remained at normal levels thereafter. During the first two postoperative days, the patient was maintained in fluid balance with plasma, blood, saline and Ringer's solution. Blood chloride levels were normal throughout the postoperative period and the hematocrit reading declined gradually from 58 preoperatively to 52 in 24 hours and then to normal values in 72 hours postoperatively. The patient has had a satisfactory recovery from his perforation and laparotomy.

COMMENT

Several problems confronted us in this case. The patient was seen by members of the medical and surgical services, and there was general agreement as to the hopeless prognosis because of the patient's age (73 years), the time elapsed since perforation (over 24 hours) and the profound state of shock. McElhinney and Holzer [2] report 100 per cent mortality in 11 patients who had perforation over 12 hours and systolic pressures under 100 mm. of mercury on admission. Only five of these 11 patients were able to undergo operation, and, as noted, all died. Similar experiences have been reported from other clinics.[3] The patient's condition was such that surgical intervention was impossible, and his situation seemed hopeless. The first result of the treatment was, however, an immediate and sustained improvement in the general condition so that laparotomy could be performed.

The Department of Medical Research of Winthrop-Stearns, Inc., supplied the arterenol used in this work.

[1] Goldenberg, M.; Pines, K. L.; Baldwin, E. de F.; Greene, D. G., and Roh, C. E.: Hemodynamic Response of Man to Nor-Epinephrine and Epinephrine and Its Relation to Problem of Hypertension, Am. J. Med. 5:792 (Dec.) 1948.

[2] McElhinney, W. T., and Holzer, C. E., Jr.: Factors Influencing Mortality from Acute Perforated Peptic Ulcers, Surg., Gynec. & Obst. 87:85 (July) 1948.

[3] DeBakey, M.: Acute Perforated Gastroduodenal Ulceration: Statistical Analysis and Review of Literature, Surgery 8:852 (Nov.) 1940.

The dosage of arterenol administered was calculated roughly on the basis of 0.2 micrograms per kilogram of body weight a minute, as suggested by Goldenberg,[1] and it was administered by constant intravenous drip. The concentration of solution was 2 mg. per liter or 2 micrograms per cubic centimeter. The dosage administered was only approximate, since our infusion set was not calibrated. We measured the number of drops given per minute and regulated the dose by regulating the rate of infusion, being guided by the level of arterial pressure.

Occasionally it was necessary to increase the rate of flow because of a spontaneous drop in tension. It should be noted that when the infusion was stopped on two occasions, the blood pressure dropped rapidly to unobtainable levels. This observation confirms that of others,[4] that the action of arterenol is very short-lived and that this fact is in part responsible for the ease with which its effect can be controlled.

During these changes in blood pressure, the pulse rate remained fairly constant. While this is contrary to previous observations, our patient was in a complicated physiological state not comparable to that in the subjects previously studied by others. The constancy of the pulse rate of between 120 and 130 beats a minute, whether or not the patient appeared to be in shock, was one of our guiding signs as to his true state. The fall of the pulse rate to 100 suggested that improvement was taking place and accordingly that it would be safe to discontinue the infusion. This proved to be correct.

Throughout the operation and for 32 hours thereafter, it was possible to maintain the patient's blood pressure at normal levels until there was reversal of whatever vasodepressor mechanisms were active during the period of shock. It is important that so long as the blood pressure was maintained at normal levels this man did not have any of the symptoms usually associated with shock. It should also be noted that within the first 24 hours after operation sufficient return of spontaneous vasomotor tone had not occurred to permit cessation of the medication. After 38 hours, when the pulse rate had slowed to 100, it was possible to stop the infusion. Apparently then, arterenol does provide vasomotor tone in the shock patient and does not prevent the repair of the normal vasomotor mechanisms following shock.

Goldenberg [1] has noted that after the intravenous injection of arterenol there is an elevation of the blood pressure, systolic and diastolic, with an over-all increase in peripheral resistance. Concurrent with these changes, there is a slowing of the pulse rate. The cardiac output is not significantly increased.

In shock, during the early phases, there is an over-all increase in vascular tonus, which becomes progressively impaired until in the last, or irreversible, phase there is a loss of small vessel tone and pooling of blood in these channels.[5] Under these conditions, the administration of arterenol may be a rational therapy for shock. Accordingly, Goldenberg,[4b] *in* a preliminary report, has cited the use of this compound in the hypotension that occasionally occurs after thoracolumbar sympathectomy and also in two cases of hemorrhagic shock, with good results.

From our single experience, it appears that this compound may well turn out to be extremely useful in shock. Its action is prompt, predictable and easily controlled. Its value in various clinical types of shock is currently under investigation.

A word of caution is necessary. Because of the prompt response to arterenol, the cause of the shock must be ascertained prior to treatment. Under arterenol therapy, a concealed hemorrhage would continue unchecked and might be aggravated by the drug.

SUMMARY

A patient with perforated peptic ulcer, who was inoperable because of profound shock, was treated with arterenol (nor-epinephrine). The shock state was rapidly relieved by this drug so that laparotomy and repair became possible. This compound has a marked but easily controllable pressor effect, which proved, in this case, to be lifesaving. It seems a powerful addition to therapy.

EVALUATION OF CLINICAL METHODS IN GASTROINTESTINAL DISEASE

LIVER FUNCTION TESTS IN PEPTIC ULCER

A. Allen Goldbloom, M.D.
Abraham Lieberson, M.D.
and
Aaron Silver, M.D., New York

There has been increasing mention in the literature of the occurrence of liver damage in peptic ulcer, as shown experimentally,[1] pathologically,[2] and clinically by biopsy [3] and liver-function tests.[4] This important question of the frequency of occurrence of liver damage in peptic ulcer concerns all of us not only from the diagnostic but also from the therapeutic and preventive points of view. It particularly concerns my co-authors and me in our investigation [5] of a modern routine for

the complete study of a patient with gastrointestinal disease. If liver damage is a frequent accompaniment of peptic ulcer, liver function studies and perhaps even liver biopsies should be included in the routine study of peptic ulcer cases.

To help determine just how important a role liver damage plays in peptic ulcer, we reviewed the last 70 consecutive cases of peptic ulcer on the medical wards of Beth Israel and Metropolitan Hospitals, New York City.

The clinical diagnosis of peptic ulcer was confirmed in each case by an X-ray showing a deformed duodenum. The study of liver function in most patients included icteric indexes, cephalin-cholesterol flocculation, thymol turbidity, sulfobromophthalein (bromsulphalein®) sodium tests, cholesterol and cholesterol ester determinations, proteins, and albumin-globulin ratios. An icteric index above 7 was considered abnormal, as were a cephalin-cholesterol flocculation of 3 + or higher in 48 hr.; thymal turbidity above 3.5 units; a total cholesterol level of above 250, a cholesterol ester ratio below 0.50; a total protein value below 5.2 gm. and an albumin-globulin ratio below 1.3:1. The results of the tests of the 70 peptic ulcer patients can be briefly summarized as follows:

The icteric index averaged 3.8. It was above the normal limit of 7 in only two cases. One of these patients, although considered clinically to have an uncomplicated peptic ulcer, was shown at operation to have an obstructive lesion penetrating into the pancreas. The mild degree of icterus (8.3) present was probably connected with this complication. The other patient had gallstones as well as duodenal and gastric ulcers. The elevated icteric index (8.1) and elevated cholesterol (257) were more likely due to the cholelithiasis and gall bladder disturbances than to the ulcers.

The cephalin-cholesterol flocculation tests averaged 1 + to 2 + and were abnormal in only six cases. The ulcer was complicated in five of these. The cephalin-cholesterol flocculation test was elevated (3 +) in only one patient with uncomplicated peptic ulcer.

The thymol turbidity tests averaged 2.0 units. It was above the normal limit of 3.5 units in three cases. In only one of these cases was the peptic ulcer uncomplicated.

The sulfobromophthalein tests, total cholesterol, cholesterol esters, total proteins, and albumin and globulin ratios were essentially normal in every case.

Rafsky and others [4i] found hypoproteinemia in 21 of their 50 peptic ulcer cases. They considered the total serum proteins below 6.0 gm. as abnormal. Their results would be much closer to ours if they accepted our figure of 5.3 gm. as the lower limit of normal.

The results of our tests show little or no impairment of liver function in peptic ulcer, whether the test be for the excretory, metabolic or inflammatory functions. This is in direct contrast to the investigations of Mateer and others,[3b] who frequently found liver damage in peptic ulcer patients, especially when pathological studies (punch biopsy) supplemented the liver-function tests. Mateer's 31 cases were all operative, and the changes seen by liver biopsy at operation may have been due to anoxia of the anesthesia, as is suggested by the studies of liver damage in shock and anoxia that Gillman and Gillman [6] report on.

It is also important to differentiate the noncomplicated peptic ulcer cases of our medical practice from the complicated surgical cases that Mateer reported. By "complicated" is meant a chronic ulcer that may have penetrated or formed adhesions to the surrounding organs, or may have produced secondary involvement of other organs such as the gall bladder. In such circumstances one realizes that the liver may readily be affected by ascending infection or secondary inflammatory change. Also, in a case of stenosing peptic ulcer such secondary hepatic inflammatory changes may result. In a case of simple, uncomplicated peptic ulcer there is much less liklihood of concomitant or resultant liver damage.

SUMMARY AND CONCLUSIONS

Some observers have encountered liver changes in cases of peptic ulcer. However no distinction was made between complicated and uncomplicated peptic ulcer.

Chronic peptic ulcers of the complicated type may occasionally produce secondary effects upon the liver, but simple noncomplicated peptic ulcers generally will produce no change upon the liver, as shown by liver function tests.

Liver function tests are not essential to the complete routine study of peptic ulcer cases.

TOXIC REACTIONS TO MERALLURIDE INJECTION (MERCUHYDRIN® SODIUM SOLUTION)

Gerald A. Reeves, M.D., Topeka, Kan.

A wide variety of toxic reactions following the use of mercurial diuretics has been reported. Although most of these reactions have been of a mild nature and have occurred infrequently in relation to the widespread use

---

Resident in Internal Medicine, Medical Service, Winter Veterans Administration Hospital.

Sponsored by the Veterans Administration and published with the approval of the Chief Medical Director. The statements and conclusions published by the author are the result of his own study and do not necessarily reflect the opinion or policy of the Veterans Administration.

of mercurial diuretics, a number of fatal reactions are now well documented. With the introduction of locally less irritating preparations, the intramuscular route of administration has proved to be less toxic. Meralluride injection (mercuhydrin® sodium solution) is one such preparation in wide clinical use. Reports of nine cases of untoward reactions to meralluride injection were found in the literature. These included one case of acute dehydration,[1] three fatal cases of toxic nephrosis,[2] and five cases with reactions of an allergic nature.[3]

The following case is reported as another instance of severe hypersensitivity to meralluride injection, with subsequent successful use of mercaptomerin (thiomerin®) sodium.

REPORT OF A CASE

A 53 year old white male auditor was admitted to Winter Veterans Administration Hospital because of marked pulmonary congestion and mild peripheral edema due to long standing hypertensive cardiovascular disease. His blood pressure on admission was 156 mm. systolic and 110 mm. diastolic. Admission blood counts were normal, but the corrected sedimentation rate (Wintrobe method) was elevated to 24 mm. per hour. Repeated urinalyses were normal, and concentrations to specific gravity 1.030 were reached on routine specimens. Nonprotein nitrogen was 40 mg. per 100 cc. An electrocardiogram revealed left bundle branch block.

The patient was placed on strict bed rest and a low salt diet. His digitalis dosage was increased, and he was given intramuscular injections of 2 cc. of meralluride daily at 9:00 a. m. The edema improved. After the eleventh meralluride injection, the patient complained of vague retrosternal pain, and his temperature rose to 100.6 F. by 4:00 p. m. and 101.6 F. at 8:00 p. m. The following morning he was afebrile and asymptomatic. His twelfth injection was given at the usual time. A sudden severe shaking chill began at 3:30 p. m., followed by fever to 103 F. Again the following morning he was afebrile but complained of weakness and aching in the thigh muscles. The leukocyte count that morning was 5,300, with a normal differential count. The urine was normal and the nonprotein nitrogen 47 mg. per 100 cc. He received no meralluride injection that day and remained afebrile. The next day, his fourteenth in the hospital, he received 1 cc. of meralluride intramuscularly at 9:00 a. m. Within one hour he complained of intense burning of the palms and subungual regions of the fingers. Generalized aching in the back, thighs and legs followed. By 1:00 p. m. he was in another shaking chill, and at 4:00 p. m. his temperature was 103.8 F., his pulse rate 104, and his blood pressure 98 mm. systolic and 70 mm. diastolic. He appeared cyanotic and was very apprehensive. Morphine and oxygen were administered. The temperature returned to normal by the following noon, and only weakness remained. Urinalysis this day showed 1 + albumin and 1 to 3 hyaline casts per high power field in the centrifuged sediment. Subsequent urinalyses were normal. The patient made a gradual recovery, complicated by pulmonary infarction on the twenty-fifth hospital day, and was discharged after 88 days. No further meralluride injection was given.

He was readmitted four and one-half months later, again in moderate pulmonary congestion and minimal peripheral edema. Along with his previous nonmercurial therapy, a trial dose of 0.1 cc. of mercaptomerin sodium was administered subcutaneously without reaction. Then 1 cc. of mercaptomerin sodium was given subcutaneously daily for a week with no ill effects. Again the edema improved.

COMMENT

In this case, as in several others recorded in the literature, premonitory symptoms of a milder nature after injection of the mercurial diuretic were present prior to the severe reaction and recognition of the hypersensitivity. Earlier recognition hinges on one's keeping in mind the possibility of hypersensitivity to mercurial diuretics when dealing with unexpected febrile reactions in patients receiving such diuretics. This patient's first two reactions posed a diagnostic problem—pneumonia, pulmonary embolism, and myocardial infarction being considered.

SUMMARY

A patient displaying severe toxic reactions to meralluride injection did not display similar reactions to mercaptomerin sodium.

UREMIA COMPLICATING LEUKEMIA CHEMOTHERAPY

REPORT OF A CASE TREATED WITH TRIETHYLENE MELAMINE

Sheldon C. Kravitz, M.D., Henry D. Diamond, M.D.
and
Lloyd F. Craver, M.D., New York

The increase in endogenous uric acid production in leukemic patients has long been a fact of considerable interest. The combination of even further production of endogenous uric acid induced by therapy and renal insufficiency is one which has been observed to lead to serious and, at times, fatal complications.[1] With newer chemotherapeutic agents in use for the treatment of the lymphomas and leukemias, drugs which are capable of depressing the white blood cell count more rapidly than x-rays, there is need for increased awareness of the possibility of uric acid obstruction of the urinary tract with subsequent uremia. We believe the following to be a case in point.

REPORT OF A CASE

C. M., a white woman aged 54, was first seen in the Diagnostic Clinic of Memorial Hospital on May 17, 1949. She gave a history of abdominal pain and progressive weight loss of one and one-half years' duration. In February, 1948, she had been hospitalized elsewhere and was found to have hepatosplenomegaly, marked leukocytosis, and anemia. A diagnosis of chronic myelogenous leukemia was made, and the patient was subsequently treated with blood transfusions, a short trial of urethan, and, finally, x-ray treatments to the spleen. Because of progression of her symptoms, she was referred to Memorial Hospital, where the diagnosis was confirmed. An incidental finding on rectal examination was a rectal polyp which was examined histopathologically and proved to be adenocarcinoma of the rectum, grade II. This was first treated with high voltage x-rays. Following this, the leukemia was treated with x-rays to the spleen, and the patient was improved sufficiently to permit an operation for the rectal

cancer. On July 2, 1949, an anterior resection of the rectum was carried out by Dr. Lucille Loseke, assistant attending surgeon on the Rectal Service of Memorial Hospital, and a primary end-to-end anastomosis of the large bowel was performed. The patient was discharged in relatively good condition on Aug. 20, 1949, one month postoperatively.

In the outpatient department she required x-ray treatments to the spleen on two separate occasions. But in May, 1950, the liver and spleen became tremendously enlarged, and this was associated with loss of appetite, chills and fever. Readmitted to Memorial Hospital on May 20, 1950, the patient appeared chronically and severely ill. Her spleen filled the entire left side of her abdomen, extending down to the inguinal ligament and reaching 3 cm. to the right of the umbilicus. Her liver was palpable 6 cm. below the right costal margin. Her hemoglobin value was 8.6 gm., red blood cell count 3,100,000 per cubic millimeter, white blood cell count 132,000 per cubic millimeter, and platelets 99,000 per cubic millimeter. Her bone marrow revealed the typical picture of chronic myelogenous leukemia with depressed erythroid activity. Urinalysis was essentially unremarkable. Blood urea nitrogen was 14 mg. per 100 cc.

The patient was given 1000 cc. of packed red blood cells which brought her hemoglobin value up to 11.3 gm. On four successive days, from May 28 to May 31, she was given 5 mg. of triethylene melamine (TEM) by oral administration (fig. 1). On the third day of therapy the patient began to complain of lower abdominal cramps, bladder urgency, dysuria, and oliguria. Her temperature was elevated to 102 F. Her white blood cell count fell precipitously from the pretreatment level of 170,000 to 35,800 per cubic millimeter five days after the first dose of triethylene melamine. The patient was catheterized and found to have hematuria and uric acid crystalluria. Intravenous pylograms showed no concentration of dye on either side. On June 2, 1950, the patient was examined by cystoscope and "sand" was seen exuding from the right ureteral orifice. A catheter could not be passed up the right ureter. One was passed up the left ureter and a retrograde pyelogram revealed a hydronephrotic left kidney. Blood urea nitrogen drawn the following day was found to be 140 mg. per 100 cc. and the serum uric acid was 26 mg. per 100 cc. Despite intravenous administration of fluids and alkalinizing solutions, oliguria and azotemia persisted. On June 6, 1950, the patient was again examined by cystocope and the uric acid crystals could be seen to swirl as distilled water was flushed into the bladder. This time it was possible to catheterize both ureters and the catheters were left indwelling. (The cystoscopies were performed by Drs. Willet Whitmore and Carl Schmidlapp, assistant attending surgeons on the Urological Service.) This was attended by a good diuresis, and in 11 days, during which time fluids were forced and the urine kept alkaline by oral administration of sodium bicarbonate, the patient came out of uremia. Her blood urea nitrogen fell to 19 mg. per 100 cc. and her serum uric acid to 6.3 mg. per 100 cc. Despite the fact that she received no more triethylene melamine, her white blood cell count continued to fall progressively until it reached 5,400 per cubic millimeter. The fall in the white blood cell count was associated with a profound decrease in the size of the spleen to 10 cm. below the left costal margin from the previously described dimensions. After the recovery from her uremia, the patient improved symptomatically and was discharged on June 23, 1950, with a hemoglobin value of 13.5 gm., white blood cell count of 12,000 per cubic millimeter, blood urea nitrogen of 9 mg. per 100 cc., and a serum uric acid of 4.9 mg. per 100 cc. Her spleen was at the level of the umbilicus. Her urinary output was satisfactory.

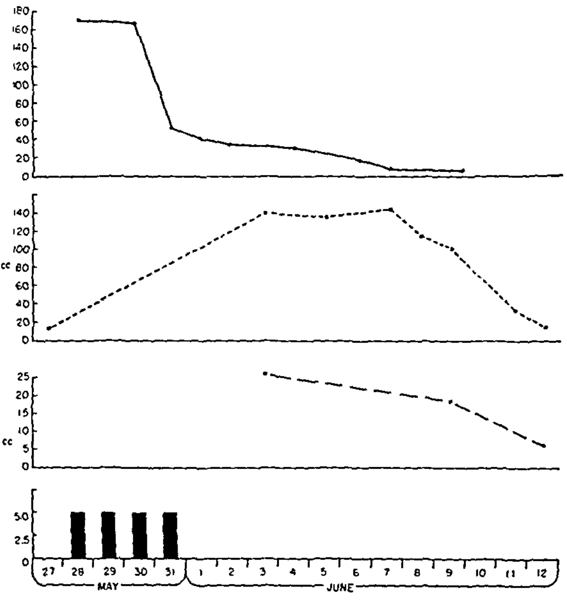

Fig. 1.—Chart showing the fall in the white blood cell count, blood urea nitrogen, and serum uric acid after administration of triethylene melamine.

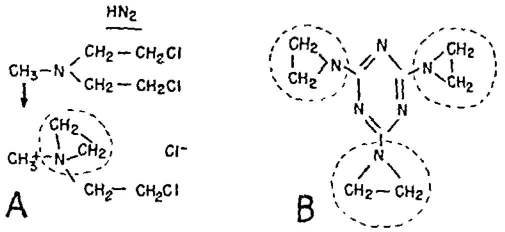

Fig. 2.—Relationship between HN_2 and triethylene melamine. A, ethylenimonium transformation of HN_2. B, triethylene melamine. (Diagram shown through the courtesy of Dr. David Karnofsky.)

The rest of the course of this patient is not pertinent to this case report. In brief, she was subsequently readmitted to Memorial Hospital on Aug. 10, 1950, for relapse of her leukemia, and died on Sept. 4, 1950, having had an attack of acute pulmonary edema three days prior to her death. Permission for an autopsy was not obtained.

COMMENT

Triethylene melamine is one of the compounds used in screening tests for effectiveness against the growth of animal tumors, by the Chemotherapy Division of the Sloan-Kettering Institute of the Memorial Cancer Center. The early results of the use of this drug were reported in a preliminary communication by Rhoads and others.[2] A more comprehensive report by Karnofsky and his associates has recently been published.[3] (This case is included in their series.)

Triethylene melamine is thought to be chemically related to nitrogen mustard (HN_2) by virtue of the ethylenimonium transformation that HN_2 undergoes in the body (fig. 2). It is the ethylene-imine ring which is thought to be the active grouping in both compounds. Triethylene melamine has been found to have actions similar to those seen with HN_2 in much the same range of diseases. The advantages of triethylene melamine are that it can be given by oral administration, smaller amounts of the drug can be used, and fewer unpleasant side effects of the kind obtained with HN_2 are present. Bone marrow depression can be serious with both drugs.

Triethylene melamine was chosen for use in this case because, despite recent x-ray treatment to the spleen, the disease was rapidly progressive, manifesting marked constitutional symptoms, and HN_2 seemed to be a drastic drug to be used on a woman who was already nauseated, vomiting, weak, and anorexic. The rapid fall in total white blood cell count and the diminution in the size of the spleen following the administration of 20 mg. of triethylene melamine given over a four-day period is apparent from the case report. The rapidity and extent of response are a little unusual following this dose in chronic myelogenous leukemia, but may occasionally be seen, and point up the variability with which patients react to oral triethylene melamine and the meticulous care which is necessary in the administration of the drug.

[3] Karnofsky, D. A.; Burchenal, J. H.; Armistead, G. C., Jr.; Southam, C. M.; Bernstein, J. L.; Craver, L. F., and Rhoads, C. P.: Triethylene Melamine in Treatment of Neoplastic Disease: Compound with Nitrogen-Mustard-like Activity Suitable for Oral and Intravenous Use, A. M. A. Arch. Int. Med 87: 477 (April) 1951.

The hyperuricemia which was associated with the precipitous fall in the white blood cell count led to an increased renal output of uric acid and subsequent obstructive uremia by uric acid crystals. This series of events corresponds with cases of similar nature reported following x-ray therapy, but the onset of uremia was more rapid in this case. It appears that simple measures can be taken in an attempt to prevent such obstruction of the urinary tract. There should be adequate knowledge of the renal function of all leukemic patients prior to therapy. A satisfactory fluid intake should be maintained during treatment, and if the uric acid is high in the blood, purines should be curtailed in the diet. The urine should be kept alkaline to make the uric acid crystals more soluble. If obstruction occurs, attempts at catheterization of the ureters should be carried out, and antibiotics should be administered to combat the infection which invariably accompanies obstruction in the urinary tract. These measures were carried out in the case reported, and success in overcoming the ureteral obstruction and uremia was achieved.

PRACTICAL SYSTEM FOR THORACENTESIS USING THE BLOOD DONOR SET

Robert D. Beech, M.D., Salt Lake City

Thoracentesis should be a simple, sterile, and nontraumatic procedure. The use of the standard blood donor set permits the attainment of these criteria. The method is a revival of the old Potain principle and is particularly applicable to the aspiration of serous effusions.

PROCEDURE

The 600 cc. vacuum flasks and the tubing and needles for obtaining donor blood are utilized. The tubing is clamped with a curved forceps, and one of the needles is inserted through the cap of the flask. After preparing the skin and anesthetizing the tissues of the chest wall, the other needle is introduced to a point just within the parietal pleura. The clamp is partially released to permit a moderate rate of flow; a screw-clamp is helpful in maintaining the optimum rate. The tubing is clamped shut when the vacuum is exausted and while the needle is transferred to a second or third bottle.

ADVANTAGES

The system described above using the blood donor set has many advantages.

1. The aspirated fluid is available for study in sterile, noncoagulated form.
2. The patient and the physician are spared the tugging and time involved in the usual syringe and stopcock method. The tubing is compressed, however, to prevent unduly rapid removal of the fluid.
3. Lacerations are frequently inflicted on the visceral pleura with the long sharp instrument on the traditional thoracentesis tray. The shorter needle of the donor set is a reminder that the chest wall is less than 1 in. (2.5 cm.) in thickness in the posterior or midaxillary line of the average slender adult. If the patient is muscular or obese, the tubing may be reversed and the longer needle employed.

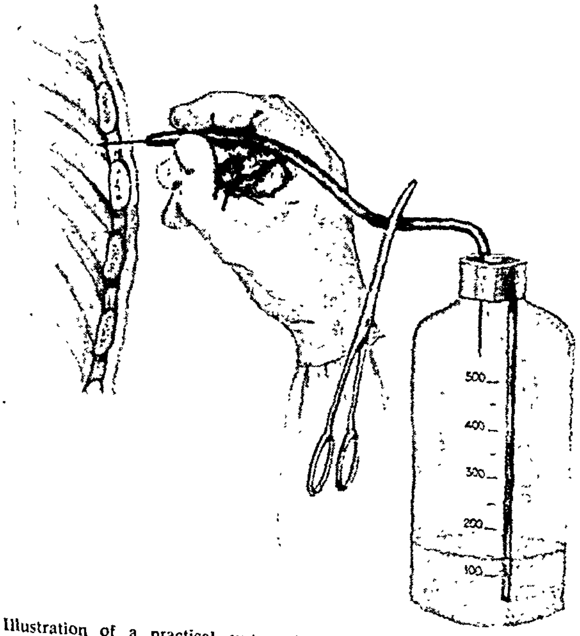

Illustration of a practical system for thoracentesis using the blood donor set.

4. Pneumothorax is avoided with difficulty when the stopcock and syringe are used, but does not occur in the presence of constant suction transmitted from the vacuum flask. For the same reason there is less chance of contaminating the pleural cavity.

CONCLUSION

The ordinary blood donor set may be used to perform thoracentesis simply and efficiently.

Antibiotic Antagonism.—There appears to be an antagonistic effect between penicillin and aureomycin or chloramphenicol. In other words, penicillin is more effective alone than in combination with either aureomycin or chloramphenicol. This is thought to be due to the fact that aureomycin and chloramphenicol are *bacteriostatic*, thus inhibiting the multiplication of the bacteria. This slows the action of penicillin, which is known to be most effective against bacteria in the rapidly growing phase.—William E. Wellman, M.D., Combinations of Antibiotics in the Treatment of Infectious Diseases, *Minnesota Medicine*, June, 1951.

COMMUNISTIC TEACHING IN SCHOOLS

A resolution concerning communism in schools which was adopted by the House of Delegates of the American Medical Association at its 1951 meeting in Atlantic City has raised some discussion concerning its intent. Some who have read the resolution reported in THE JOURNAL (June 30, 1951, p. 849) have asked whether this represents an imputation of the public school system of this country or whether it is intended only to draw attention to that minority group of teachers which by subversive teachings embarrasses the loyal educators. Most educators have contributed much to community life and the welfare of the country and have been associated closely and willingly with the other professional groups, particularly those interested in health.

The House of Delegates did not intend to arraign the public school system. Most physicians are products of this system. Nor was there any intention of accusing the majority of school educators of being subversively inclined. In fact, physicians are aware that the American Association of School Administrators together with the National Council of Chief State School Officers joined forces with the American Medical Association and other professional and civic groups to oppose the President's Reorganization Plan No. 1 in 1949 and Plan No. 27 in 1950. Furthermore, the American Association of School Administrators and the National Education Association have made public announcements protesting the hiring of communist teachers. Many physicians and educators have worked industriously for many years to develop programs of mutual interest.

The medical profession has confidence in the teaching profession and believes that it consists mainly of a group of earnest, hard working individuals devoted to the ideals of democracy. However, in any large organization there are certain individuals who do things which do not bring credit to the organization. This is true in practically any aspect of community life. Whether the cause for criticism is due to lack of understanding or a determined, disloyal attempt to undermine the country's standards is not always apparent. The situation can be clarified best by each group studying its particular problem so that it may take whatever action is appropriate.

The American Medical Association, its constituent state associations, component county associations, and other groups for some time have been waging war against attempts to socialize medicine. Such socialization would be just one phase of the development of a program to collectivize and control by federal government all phases of the economic and social structure of this nation. The control of the educational system and the influencing of educators would be a primary objective in this program in spite of the fact that only a free educational system can truly be educational in a democratic sense. Freedom of this system must be protected at all costs. The American Medical Association therefore deplores the efforts of the small but determined and vocal minority of communist-inspired conspirators to impair the good repute of the schools in this country. The members of the Association as citizens and as practitioners, who have experienced the benefits of this nation's schools and whose children are now attending these schools, do not want them destroyed as instruments of democratic government.

RETIREMENT BENEFITS FOR PHYSICIANS

On two occasions the House of Delegates of the American Medical Association has expressed unanimous approval of a suggested amendment to the federal internal revenue laws to permit nonsalaried physicians and other self-employed taxpayers to set up for themselves a retirement benefits program out of income the tax on which would be deferred until the benefits are received. Such a privilege is now extended by federal law to taxpayers who are associated with corporations or who otherwise function as employees but not to the self-employed, who, because of legal, ethical, or other considerations, cannot function as corporate entities. This tax discrimination affects adversely not only physicians but the self-employed of other professional groups, such as lawyers and dentists. For several years, the directors of the Bureau of Medical Economic Research and of the Bureau of Legal Medicine and Legislation have collaborated with other organizations in the development of appropriate federal legislation; only recently they have consulted with a special committee of the American Bar Association in connection with this matter. That committee has completed a draft of legislation which was introduced in the Congress last June by Congressman Keogh, as H. R. 4371, and by Congressman Reed, as H. R. 4373. In the meantime, a new tax bill, H. R. 4473, has been progressing toward enactment. That bill passed the House of Representatives on June 22 and is being considered at the present time by the Senate Finance Committee. In order to expedite Congressional consideration of the retirement benefits proposal, Senator Ives on July 25 introduced as an amendment to the pending tax bill the substance of the Keogh-Reed legislation; this amendment is being considered by the Senate Finance Committee. Favorable action initially by the Committee and later by the Congress would remove a tax inequity that has long existed without understandable justification.

As previously pointed out in THE JOURNAL,[1] the pattern of the economic life of a physician subjects him to a proportionately greater tax burden than is borne by many other self-employed taxpayers. His period of education and training is long. His lifetime earnings are bunched into a comparatively short working lifetime, and by reason of that fact he pays more federal income taxes during his life than do members of many other groups with similar lifetime earnings. In supporting the Ives amendment, physicians are not asking for any special favors. They are suggesting only a more equitable distribution of the tax burden.

ERADICATION OF MALARIA

It is indicative of the progress in the field of malaria that the 1950 Symposium of the National Malaria Society [1] was concerned with "Nation-Wide Malaria Eradication Projects in the Americas" rather than with "control" of malaria, as in the past. The concept of eradication of a disease implies, according to Soper,[1e] that the roots of infection are so destroyed that the disease will not reappear, in the absence of reintroduction, even though control measures be discontinued. The first suggestion for the "eradication" of malaria according to Andrews,[1a] was made by Dr. Frederick L. Hoffman in 1915, although he probably used the word eradication in the sense of control rather than of complete elimination of the disease. In his presentation, Andrews credits Dr. L. L. Williams Jr. with much of the antimalaria activities in the United States. The Public Health Service, with which Williams was associated, has initiated field investigations, promoted the development of state-level malaria survey and control teams, and organized coordinated major malaria control projects in this country. During World War II, the Office of Malaria Control established by Williams assisted the states in reducing the malaria hazard to trainees and workers around the areas of military importance. Drainage, filling, killing of larvae, entomologic exploration and inspection, and educational activities were carried out by this organization near some 2,200 localities of military importance in 18 different states. These activities are credited with preventing malaria in this country from interfering with the war effort and aborting the increase in national malaria incidence predicted for the early or middle forties.

The military use of DDT as a residual insecticide has established its antimalarial effectiveness and economy, and in 1945 the compound was made available to the states through the Public Health Service, specifically to prevent the transmission of imported malaria. It was sprayed on the interior walls and ceilings of rural homes and privies in counties where relatively high malaria mortality was experienced during the five years preceding World War II. This activity was known as the Extended Malaria Control Program and was carried on for two years.

The National Malaria Eradication Program was initiated in 1947. In planning the program for this country, it was realized that the vectoral species of Anopheles could not be completely annihilated. The elimination of all malaria parasites from the population by mass treatment was also considered difficult of achievement. The approach to the problem was based on the elimination of endemicity and the prevention of its reestablishment. It was believed that, if the numbers of malaria parasite carriers and of vectoral mosquitoes could be reduced at the same time, transmission would become less and less likely. This program could be carried on until ultimately endemic malaria would be eradicated. The decline in transmission was to be achieved by promoting improved diagnosis and treatment of the disease and by reducing the household density of Anopheles with residual insecticides. The second phase of the eradication program to prevent the recurrence of endemicity, involved surveillance and prevention teams assigned to state health departments. The Public Health Service had the cooperation of 13 states concerned in this National Malaria Eradication Program.

In the usual procedure, 5% DDT in a triton®-xylene-water emulsion is applied to internal surfaces of homes and privies at the approximate rate of 200 mg. of DDT per square foot. A review of the reported statistics on malaria mortality and morbidity, of routine diagnostic and survey blood examinations, and of case appraisals supports the contention that our endemic malaria has declined to a very low level. Andrews feels that the reduction of primary malaria in this country during the last 20 years is due in large part to the use of insecticides in the home.

The results with residual DDT spraying of dwellings were even more spectacular in some of the South American republics. According to Gabaldon,[1b] large-scale introduction of the method in Venezuela in 1945 resulted in a decided reduction in malaria incidence. The malaria death rate fell from a median of 112 per 100,000 in 1941-1945 to nine in 1949. Malaria was prevalent in British Guiana in 1947. According to Giglioli,[1c] Anopheles darlingi, the principal transmitter of malaria in the colony, has completely disappeared from all areas in which systematic residual DDT spraying was done. The results of a nationwide malaria control program based on house spraying with DDT in Brazil were reported by Pinotti.[1d] The initial effect was disappearance of all Anopheles from the interior of human dwellings. This development was observed with all five of the Brazilian vector species after the first treatment with DDT. The results suggest that eradication of malaria from large sections of the country may eventually be achieved.

This symposium of the National Malaria Society on "Nation-Wide Malaria Eradication Projects in the Americas," according to Soper,[1e] makes it apparent that the great bulk of the malaria of the Americas is readily suppressed through residual domiciliary spraying. For the first time, there exists a single, efficient, and economical attack on malaria which can be standardized and applied to almost all malarious areas of the Americas.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

As physicians, we are all more or less aware of the extensive scientific activities of our American Medical Association. Most of us, however, are not so familiar with the many valuable public services which the Association renders, because they do not affect us so directly. One of the most important of these is the Association's work in health education of the public.

Our Association pioneered in this field, turning out authentic, interesting health information long before most other health agencies had recognized its value. The A. M. A.'s Bureau of Health Education was first established in 1911 as the Council on Health and Public Instruction. It has been functioning continuously ever since, although it has undergone several reorganizations and name changes.

The present director of the Bureau is Dr. W. W. Bauer, an internationally known leader in public health education. Dr. Bauer, who also edits *Today's Health*, received the Elisabeth Severance Prentiss National Award in Health Education from the Cleveland Health Museum in 1947, and in 1949 he spent three months in Germany as a visiting expert in public health with the American Military Government. He is the author or co-author of 16 books in the health field, and the list of organizations which he serves as health consultant is impressive. Assisting Dr. Bauer with the professional work of the Bureau are two other physicians and an educator, all of whom have extensive experience in the health education field.

The oldest of the Bureau's many activities is answering medical questions sent in to the A. M. A. by laymen. From 12,000 to 15,000 such letters are received annually, averaging about 140 questions per 100 letters. All of them are answered under the supervision of a physician from information in the medical literature. Occasionally unusual or difficult questions are referred to highly qualified consultants who render this service freely and anonymously to the Association.

Another important activity of the Bureau is health education by radio. The A. M. A. entered this field in 1925 with two broadcasts every week day over a Chicago station, one of which was also channeled to the CBS network. In 1933 the Association began presenting weekly health talks over the NBC network, and over a period of years furnished authentic health information on thousands of subjects. This series twice won first place awards from the Institute for Radio in Education, held annually at Ohio State University. Because of the advent of television, which cut the value of network radio, the A. M. A. in 1949 dropped this series in favor of occasional documentary-type network shows.

Another important phase of the Bureau's work in radio started in 1930, when it began preparing and distributing radio scripts for use by local medical societies. This eventually grew into a library of some 1,000 scripts, and the service was continued until World War II, when the heavy drain on physicians' time made the use of scripts difficult. Since medical societies still wanted to continue broadcasting, the Bureau in 1941 began recording health programs. It currently has 25 different 13-week transcribed programs available on a loan basis to medical societies for use on local radio programs.

Television has offered a dramatic new challenge for health education. In 1947 the A. M. A. supervised a series of experimental telecasts on a Chicago station which were similar in character to the present highly successful Johns Hopkins "Science Review." Since then the Bureau has made the first medical network telecast, on atomic energy in medicine, in 1949, and produced a kinescoped dramatic telecast, "Dr. Webb of Horseshoe Bend," in 1950. The latter was televised in 40 of 65 communities having television facilities. To assist local medical societies, the Bureau has prepared packets of sample television scripts with full instructions for presenting "live" shows and also a Television Handbook with general pointers on television. Currently, the Bureau and the A. M. A. Committee on Medical Motion Pictures are conducting an investigation into the use of available health films on television and the possible production of such films especially for television.

In addition to radio, television, and the answering of mail inquiries, the Bureau of Health Education reaches the public through production of pamphlets. Some of these are reprints from *Today's Health;* many are developed by the staff. All are available at cost. The 500,000 copies which the Bureau distributes yearly cover a wide variety of health subjects and are used by medical societies at public meetings, fairs and expositions, and by individual physicians to lighten the load of patient questions.

One of the Bureau's most outstanding contributions has been made in the field of school health. At the time it was first established, the Bureau set up a Joint Committee on Health Problems in Education with the National Education Association. This year that committee is celebrating its 40th year of continuous growth in service and prestige. It has published, among other things, one of the most authoritative books in existence on health education and has exerted great influence through the years for improvement in all phases of school health.

Every two years since 1947, the Bureau has sponsored a National Conference on Physicians and Schools, the proceedings of which have been widely circulated and quoted. The Bureau staff also serves in a consulting capacity to practically every educational organization and through these contacts has been able to effect steady progress in school health.

I have not mentioned the many speaking engagements filled by staff members, the other invaluable contacts of the Bureau with most national organizations interested in public health, or the Bureau's pioneering work in the fight against antivivisectionists and other cults. Suffice it to say that, except for health movies, exhibits, and news releases, which are handled by other departments, there is no area of health education not covered by the Bureau.

Here is constructive, progressive work to which every A. M. A. member can point with pride. The best way we can help our Health Education Bureau is to use its services fully.

John W. Cline, M.D., San Francisco.

MEDICAL NEWS

CALIFORNIA

Loans for Junior Physicians.—The San Francisco Medical Society has established a loan fund for interns and residents in the City and County of San Francisco. Ten thousand dollars has been made available for use in assisting junior physicians in need of financial help to complete a previously planned program of training. All applications are to be considered in the strictest confidence and without unnecessary delay. Applicants are limited to one loan each year except in unusual cases to be determined by the committee for junior physicians and the finance committee. Notes will be signed personally with no co-signers or guarantors required. The principal of the loan is to be repaid within two years after starting practice or, in most cases, within a period of five years after the activation of the loan. The prevailing rate of savings bank interest at the time of the loan will be charged.

COLORADO

State Medical Meeting.—The annual session of the Colorado State Medical Society will be held at the Shirley-Savoy Hotel, Denver, Sept. 18-21 under the presidency of Dr. Ervin A. Hines, Denver. Guest speakers at the general assemblies include the following:

Ralph V. Platou, New Orleans, Prenatal Influences.
Stuart W. Harrington, Rochester, Minn., Clinical Manifestations and Surgical Treatment of Carcinoma of the Breast.
Donald E. King, San Francisco, Common Mistakes in the Treatment of Common Fractures.
Maxwell M. Wintrobe, Salt Lake City, Diagnosis and Treatment of Anemia.
Wilhelm C. Hueper, Bethesda, Md., Environmental Cancer Problems in Colorado.

There will be a symposium on communicable diseases on Wednesday morning, the participants being Drs. Roy L. Cleere and John A. Lichty, Denver, Charles H. Dowding Jr., Aurora, Colo., and Joseph E. Cannon, Denver. On Friday morning the department of dermatology of the University of Colorado School of Medicine will present a symposium on lupus erythematosus. "You and Your A. M. A." will be the subject of a symposium and panel discussion Thursday afternoon. Five 10-minute papers will be given by the following officials of the American Medical Association: Dr. James R. McVay, Kansas City, Mo., Dr. Edward J. McCormick, Toledo, Ohio, Dr. Joseph D. McCarthy, Omaha, Dr. George A. Unfug, Pueblo, Colo., Dr. Frank E. Wilson, Washington, D. C., and Dr. Fred A. Humphrey, Fort Collins, Colo. There will be a question and answer period following the papers. The annual banquet will be held Friday evening. The Women's Auxiliary to the society will meet in conjunction with the association.

CONNECTICUT

Hospital Building Boom.—A survey recently completed by the state medical society shows that the biggest hospital building boom in the state's history is underway at a cost that will exceed 29 million dollars. It involves more than half of the state's 34 community hospitals and ranges from alterations to erection of completely new hospital units. The multimillion-dollar-program will provide more than 1,200 additional hospital beds and an array of new operating rooms, maternity centers, and emergency, diagnostic, and outpatient facilities, as well as laboratories, hospital pharmacies, and dietary and laundry services. The survey discloses that 90% of the 29 million dollar expansion will be paid for by voluntary contributions that already exceed $19,500,000. Government contributions under provisions of the Hill-Burton Act may account for 10%. In several instances applications for government money were not filed, the entire amount being raised locally.

The millions that are being spent are not only flowing into large city hospitals but also into hospitals in smaller communities that serve large rural areas. The survey concerns only privately supported community hospitals, municipal, state, or federal institutions. It covers construction undertaken or completed during the past year, projects currently in progress, and those scheduled to start in the next six to eight months. Among the 18 hospitals engaged in building programs, the largest single project is the new 10-floor memorial unit now under construction at the Grace-New Haven Community Hospital. The building is scheduled for completion in October, 1952, at a cost of 7 million dollars including equipment. It will provide 325 patient beds and all facilities for independent hospital operation.

ILLINOIS

Carroll County Honors Veteran Physician.—Thousands of persons from Carroll County and nearby counties in Illinois and Iowa turned out Aug. 8 to honor Dr. Joseph B. Schreiter, who has practiced in Savanna for 55 years. The ceremony included a parade, a picnic, oratory, and bestowal of various surprise honors on the 76-year-old physician. An invitation was issued to all the 4,000 persons at whose birth Dr. Schreiter has presided. The Illinois State Medical Society sent Dr. Andy Hall of Mt. Vernon, 86-year-old veteran who was chosen the outstanding general practitioner of the nation for 1950 by the American Medical Association, as principal speaker for the occasion. Also representing organized medicine of the state were Dr. C. Paul White of Kewanee, president of the Illinois State Medical Society; Dr. Harold M. Camp of Monmouth, its secretary; Dr. Charles P. Blair of Monmouth, chairman of its council; and Dr. Joseph S. Lundholm of Rockford, state councilor. Many other physicians joined the Carroll County Medical Society in honoring him. Dr. Schreiter was elected coroner in 1903 and still serves in that post, having been re-elected 11 times. He is chief of staff of the Savanna City Hospital. Despite his age and many activities, he still takes care of a substantial practice, making house calls and keeping evening office hours, although he no longer does major surgery.

Chicago

Personal.—F. Ellis Kelsey; Ph.D., associate professor of pharmacology at the University of Chicago, has been appointed director of the chemical department of the Nuclear Instrument and Chemical Corporation, Chicago.

Joins Armour Medical Staff.—Dr. Grosvenor W. Bissell, Buffalo, has joined the clinical investigation group of the medical department of the Armour Laboratories as an assistant medical director. Dr. Bissell has been full-time assistant professor of medicine at the University of Buffalo and director of the endocrinology clinic of Edward J. Meyer Memorial Hospital.

Loyal Davis to Lecture at Oxford.—Dr. Loyal Davis, professor of surgery and chairman of the department at Northwestern University Medical School, has been selected to give the Earl of Litchfield Lecture at Oxford University Oct. 10, on "The Physiological Principles Underlying the Treatment of High Diastolic Hypertension by Thiocyanates and Sympathectomy."

Chicago Heart Association Grants.—Checks totaling $81,050 have been presented to representatives of nine Chicago area medical institutions by the Chicago Heart Association for research projects in heart disease. The grants are the first from funds raised in the association's 1951 drive. The nine institutions are the University of Chicago, Northwestern University, University of Illinois, Loyola University, Chicago Medical School, Michael Reese Hospital, La Rabida Sanitarium, Herrick House, and Women and Children's Hospital for its Heart of the Home cardiac education program under Dr. Margaret H. Austin.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

IOWA

Promotions at State University.—The following persons have been promoted to the rank of assistant professor in the department of internal medicine, State University of Iowa, Iowa City: Drs. Henry E. Hamilton, Walter M. Kirkendall, Paul M. Seebohm, and Raymond F. Sheets Jr. Dr. William Ames was promoted to the rank of associate; Drs. David W. Sinton and Ernest O. Theilen were appointed instructors, and Dr. Margaret Vance was appointed fellow in metabolism. Dr. Murray Franklin resigned to take a position in the department of internal medicine at the University of Illinois, Chicago.

KANSAS

Dr. Murphy Named Chancellor.—Dr. Franklin D. Murphy, dean of the University of Kansas School of Medicine since July 1948, was named chancellor of the University of Kansas July 2, succeeding Chancellor Deane W. Malott, who resigned to become president of Cornell University, Ithaca, N. Y. During his three years as dean Dr. Murphy has strengthened the medical school faculty, and with the State Medical Society and the Farm Bureau he co-authored the Kansas Rural Health Plan, which has already begun to show results. The U. S. Junior Chamber of Commerce selected him in 1949 as one of the 10 outstanding young men of the country, and in June of this year he was elected by the House of Delegates to the Council on Medical Education and Hospitals of the American Medical Association.

MARYLAND

Test State Drivers.—State and county health departments of Maryland are now giving standard driving tests to all personnel who drive state cars in an attempt to improve their habits and reduce accidents. The actual testing was begun July 2 and by the end of August tests will have been completed in each of Maryland's 23 counties. It is expected that about 230 persons throughout the state will be tested this summer. The test, administered by a representative of the Automobile Club of Maryland, consists of three parts. The first part is a written test of traffic and driving knowledge that includes 25 questions. A practical driving test follows, with the examiner accompanying the driver on the road and making notes concerning any errors made. Finally, there is a battery of psychophysical tests which measure performance on standard testing devices. Soon after each test has been made, a report of conclusions reached and possible recommendations for corrective action are sent to the individual tested, the deputy state health officer, bureau chief, or division chief to whom the driver is directly responsible, and also to the chief of the bureau of management.

MINNESOTA

Dr. Dennis Goes to New York.—Dr. Clarence Dennis, professor of surgery at the University of Minnesota Medical School, Minneapolis, will be professor of surgery and director of general surgery, University Division, at the Kings County Hospital, Brooklyn. Dr. Dennis has successively held the positions of instructor, assistant professor, and associate professor of surgery at the University of Minnesota, and was appointed professor of surgery there in 1947.

MISSISSIPPI

Malaria in Korean Veterans.—According to Dr. Archie L. Gray, of the Mississippi State Board of Health, seven proved and two probable cases of malaria were reported in Mississippi during the first six months of 1951. All of the cases have been reported since May 24 and have occurred only in military personnel who had served in Korea. The ages of those infected ranged from 19 to 27 years. Six Plasmodium vivax infections and one Plasmodium malariae infection were confirmed by laboratory examination. Two cases in which laboratory confirmation was not obtained had received treatment a short time before blood smears were taken. Six of the cases had had suppressive treatment while in military service in Korea, and one has a suggestive history of malaria prior to military service. Dr. Gray states that the presence of this number of known cases of malaria in Mississippi is disturbing since local outbreaks may occur in the communities to which these veterans have returned.

MONTANA

State Medical Meeting.—The annual session of the Montana Medical Association will be held at the Meadow Lark Country Club, Great Falls, Sept. 13-16 under the presidency of Dr. Clyde H. Fredrickson of Missoula. Guest speakers at the scientific sessions include the following:

Robert H. Williams, Seattle, Adrenal Physiology and Therapy.
Russell R. de Alvarez, Seattle, Hysterectomy.
Thomas H. Holmes, Seattle, Life Stress and Respiratory Disorders.
K. Alvin Merendino, Seattle, Heart Surgery: An Evaluation of the Present Status with a Look into the Future.
Thomas B. Carlile Jr., Seattle, Clinical Use of Radioactive Isotopes.
Robert J. Neville, Teaneck, N. J., Staff Management of Poliomyelitis.
Kenneth A. Phelps, Minneapolis, Dangerous Complications of Tonsillectomy in Children.

There will be noon panel discussions on Thursday and Friday conducted by the guest speakers. At the banquet Friday at 7 p. m., Frank G. Dickinson, Ph.D., director, Bureau of Medical Economic Research, American Medical Association, Chicago, will speak on "The Shortage of Physicians: Phantom or Fact." Technical exhibits will be on display. The State Academy of Oto-Ophthalmology and Obstetrical and Gynecological Society, the Montana Pediatric Society, and the Montana Chapter of the American Academy of General Practice will hold dinner meetings Thursday evening. The Women's Auxiliary to the association will meet Sept. 13-15 with headquarters at the Rainbow Hotel in Great Falls.

UTAH

State Medical Meeting.—The Utah State Medical Association will hold its annual session in the Union Building at the University of Utah, Salt Lake City, Sept. 13-15 under the presidency of Dr. Vivian P. White, Salt Lake City. Out-of-state speakers include the following:

Carl A. Moyer, Dallas, Texas, General Principles of the Supportive Care of Trauma.
William J. Dieckmann, Chicago, Toxemias of Pregnancy.
Charles L. Martin, Dallas, Texas, Uterosalpingography for Treatment of Sterility in the Female.
Vernon D. E. Smith, St. Paul, Thrombo-Embolism: Post-Operative Prophylactic Anti-Coagulation Therapy.
Frank B. Walsh, Baltimore, Recent Advances in Ophthalmological Diagnosis of Systemic Disease.
Lawrence W. Kinsell, Oakland, Calif., Present Status of the Clinical Application of ACTH and Cortisone.
Arthur C. Curtis, Ann Arbor, Mich., Cutaneous Lesions as a Manifestation of Systemic Disease.
Irvine McQuarrie, Minneapolis, Spontaneous Hypoglycemosis as a Clinical Problem.

On Thursday morning there will be a surgical round table with Dr. Ralph T. Richards, Salt Lake City, as moderator, and the discussants Drs. Smith, Moyer, Dieckmann, Martin, and Walsh. A medical round table will be held Friday afternoon with Dr. Louis E. Viko acting as moderator. The discussants will be Drs. Wintrobe, Kinsell, Curtis, McQuarrie, and John Z. Bowers of Salt Lake City. The banquet will be held Friday evening in the ballroom of the Hotel Utah beginning at 7 p. m. Dr. Smith will give an illustrated lecture entitled "The Cradle of Modern Skiing."

ALASKA

Medical Election.—Officers of the Alaska Territorial Medical Association for 1951-52 include Dr. Howard G. Romig, Anchorage, president; Dr. John O. Bangeman, Wrangell, first vice president; Dr. John H. Clements, Juneau, second vice president, and Dr. William P. Blanton, Juneau, secretary-treasurer.

GENERAL

Surgical Congress.—The third annual meeting of the Southwestern Surgical Congress will be held at the Hotel Jefferson, St. Louis, Sept. 24-26. Reservations may be secured by writing directly to the hotel. Registration will begin at 12 noon Sept. 23 and at 8 a. m. on each succeeding day. There will be a $10 registration fee for non-members of the congress.

Keyes Memorial Medal.—Dr. William F. Braasch, professor of urology at the Mayo Foundation in Rochester, Minn., has been awarded the Dr. Edward L. Keyes gold medal of the American Association of Genito-Urinary Surgeons for his "outstanding

Association of Military Surgeons of the United States, Palmer House, Chicago, Oct. 8-10. Colonel James M. Phalen, Armed Forces Institute of Pathology, Washington 25, D. C., Secretary.

Colorado State Medical Society, Denver, Sept. 18-21. Mr. Harvey T. Sethman, 1612 Tremont Place, Denver 2, Executive Secretary.

Delaware, Medical *Society of, Wilmington, Oct. 8-10. Dr. Andrew* H. Gehret, 1007 Park Place, Wilmington, Secretary.

District of Columbia, Medical Society of, Hotel Statler, Washington, Oct. 1-3. Mr. Theodore Wiprud, 1718 M St. N.W., Washington, Secretary.

Kansas City Southwest Clinical Society, Municipal Auditorium, Kansas City, Mo., Oct. 1-4. Dr. Maxwell G. Berry, 630 Shukert Bldg., Kansas City, Mo., Director of Clinics.

Kentucky State Medical Association, Columbian Auditorium, Louisville, Oct. 2-5. Dr. *Bruce Underwood*, 620 S. *Third* St., Louisville 2, Secretary.

Michigan State Medical Society, Grand Rapids, Sept. 26-28, Dr. L. Fernald Foster, 606 Townsend St., Lansing 15, Secretary.

Mississippi Valley Medical Society, Peoria, Ill., Sept. 19-21. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

Montana Medical Association, Great Falls, Sept. 13-16. Mr. L. R. Hegland, 104 N. Broadway, Billings, Executive Secretary.

Nashville Postgraduate Medical Assembly, Maxwell House, Nashville, Tenn., Oct. 3-5. Dr. W. G. Kennon Jr., 647 Doctors Bldg., Nashville 3, *Secretary.*

Neurosurgical Society of America, Sun Valley, Idaho, Sept. 12-14. Dr. C. D. Hawkes, 22 N. Manassas St., Memphis 5, Tenn., Secretary.

Nevada State Medical Association, Riverside Hotel, Reno, Sept. 13-15. *Dr. Wesley W. Hall, 307 W. Sixth St., Reno, Secretary.*

New Hampshire Medical Society, Equinox House, Manchester, Vermont, Sept. 30-Oct. 2. Dr. Deering G. Smith, 44 Chester St., Nashua, Secretary.

Northeastern Section, Southeastern Surgical Congress, Lord Baltimore Hotel, Baltimore, Sept. 13-15. Dr. W. Raymond McKenzie, Medical Arts Bldg., Baltimore 1, Secretary.

North Texas-Southern Oklahoma Fall Clinical Conference, Wichita Falls, Texas, Sept. 19. Dr. W. L. Powers, 517 Hamilton Bldg., Wichita Falls, Chairman.

Oregon State Medical Society, Masonic Temple, Portland, Oct. 10-13. Dr. Robert F Miller, 833 S.W. Eleventh Ave., Portland 5, Secretary.

Pennsylvania, Medical Society of the State of, Pittsburgh, Sept. 16-20. Dr. Walter F. Donaldson, 500 Penn Ave., Pittsburgh 22, Secretary.

Southwestern Surgical Congress, Hotel Jefferson, St. Louis, Sept. 24-26. Dr. C. R. Rountree, 1227 Classen St., *Oklahoma City* 3, Secretary.

Texas Academy of General Practice, Shamrock Hotel, Houston, Texas, Sept. 10-11. Dr. B. H. Bayer, 104 E. 20th St., Houston 8, Secretary.

U. S. Chapter, International College of Surgeons, Palmer House, Chicago, Sept. 10-14. Dr. Arnold S. Jackson, 1516 Lake Shore Drive, Chicago, Executive Secretary.

Utah State Medical Association, Salt Lake City, Sept. 13-15. Dr. T. C. Weggeland, 42 S. Fifth East St., Salt Lake City, Secretary.

Vermont State Medical Society, Equinox House, Manchester, Sept. 30-Oct. 2. Dr. *James* P. Hammond, 542 Main St., Bennington, *Secretary.*

Virginia, Medical Society of, Virginia Beach, Oct. 7-10. Mr. Richard H. Nash, 1105 W. Franklin St., Richmond, Executive Secretary.

Washington State Medical Association, Olympic Hotel, Seattle, Sept. 9-12. Dr. James W. Haviland, 338 White-Henry-Stuart Bldg., Seattle, Secretary.

Western Society of Electro-Encephalography, Olympic Hotel, Seattle, Sept. 7-8. Dr. Nicholas A. Bercel, 450 N. Bedford Drive, Beverly Hills, Calif., Secretary.

Wiscnosin, State Medical *Society of, Hotel Schroeder and* Milwaukee Auditorium, Milwaukee, Oct. 1-3. Mr. Charles H. Crownhart, 704 E. Gorham St., Madison 3, Secretary.

Wyoming State Medical Society, Rock Springs, Sept. 27-29. Dr. Glenn W. Koford, 2020 Carey Ave., Cheyenne, Secretary.

INTERNATIONAL

European Congress on Rheumatism, Barcelona, Spain, Sept. 24-27. Dr. Gunnar Edströn, Lund, Sweden, Secretary.

General *Practitioners Study Club International*, Rome, *Italy*, Sept. 12-15. Dr. John O'Connell, 10300 Lackland Road, St. Louis 14, Mo., U. S. A., President.

International Anesthesia Research Society, London, England, Sept. 3-7. Mr. R. W. Cope, University College Hospital, London W.C.1, England.

International Association of Allergists, Zurich, Switzerland, Sept. 23-29. Prof. A. S. Grumbach, Hygiene Institut der Universitaet Zurich, Gloriastr. 32, Zurich, Switzerland.

International Congress of Anesthesiology, Nursing School of the Salpiettre, 47 Boul de l'Hospital, Paris, France, Sept 20-22. 12 rue de Seine, Paris 6ᵉ, France, Secretariat.

International Congress on Industrial Medicine, Instituto Superior Técnico, Lisbon, Portugal, Sept. 9-15. Dr. Luis Guerreiro, Instituto Nacional do Trabalho e *Previdência, Praça do Comercio*, Lisbon, *Secretary* General.

International Congress on Mental Health, Mexico City, Mexico, Dec. 11-19. Mrs. Grace E. O'Neill, Division of World Affairs, National Association on Mental Health, 1790 Broadway, New York 19, N. Y.

International Gerontological Congress, Hotel Jefferson, St. Louis, Mo., U. S. A., Sept. 9-14. Dr. John E. Kirk, 5600 Arsenal Street, St. Louis 9, Mo., Chairman, Program Committee.

International Poliomyelitis Congress, Copenhagen, Denmark, Sept. 3-7. *Prof.* Dr. Niels Bohr, Statens Seruminstitut, 80 Amager Blvd., Copenhagen S., Denmark, President.

International Society of Surgery, Paris, France, Sept. 24-29. Dr. L. Dejardin, 141, rue Belliard, Brussels, Belgium, Secretary General.

International Society for the Welfare of Cripples, Fifth World Congress, Stockholm, Sweden, Sept. 9-14. Mr. Donald V. Wilson, 54 E. 64th St., New York 21, N. Y., U. S. A., Executive Director.

Pan Pacific Surgical Association Congress, Honolulu, Hawaii, Nov. 7-19. Dr. Forrest J. Pinkerton, Suite 7, Young Bldg., Honolulu, Hawaii, *President.*

World Confederation for Physicial Therapy, Copenhagen, Denmark, *Sept. 7-8.*

World Medical Association, Stockholm, Sweden, Sept. 15-21. Dr. Louis H. Bauer, 2 E. 103d St., New York 29, N. Y., U. S. A., Secretary General.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various Centers. *Sept. 5-7 (Part I only). Applications must* be filed at least thirty days prior to an examination. Ex. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Oral.* Memphis, Oct. 14-17. Sec., Dr. Curtiss B. Hickcox, 80 Seymour St., Hartford 15, Conn.

American Board of Dermatology and Syphilology: *Written.* Chicago, March 1952. *Oral.* Chicago, May 1952. Final date for filing application is Feb. 1, 1952. Sec., Dr. George M. Lewis, *66* E. *66th St.*, New York 21.

American Board of Internal Medicine: *Written.* Various centers, Oct. 15. Final date for filing applications was May 1. *Oral.* The schedule of oral examinations for 1951 has been arranged on a regional basis as follows: New York, Nov. 12-15, covering Maine, Massachusetts, New Hampshire, New York and Vermont. San Francisco, Oct. 22-24, covering Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington and Wyoming. Final date for filing applications is Sept. 1.

Only candidates who have not taken an oral examination can be admitted under the schedule arranged thus far.

Oral examinations in the subspecialties will be held at the same time and place and on the same distribution.

Exec. Sec., Dr. William A. Werrell, 1 W. Main St., Madison 3.

American Board of Neurological Surgery: *Oral.* Chicago, Oct. 25-26. *Oral* Chicago, May 1952. Final date for filing applications for the May 1952 examination is Jan. 1, 1952. Sec., Dr. W. J. German, 789 Howard Ave., New Haven 4, Conn.

American Board of Obstetrics and Gynecology: *Written.* Feb. 1, 1952. Final date for filing applications is Nov. 1. *Oral.* Chicago, June 7-13, 1952. Final date for filing application is Feb. 1, 1952. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Written.* Twenty-five centers, Feb. 4-5, 1952. *Oral. Chicago, October 8-13. Sec.*, Dr. Edwin *B.* Dunphy, 56 Ivie Road, Cape Cottage, Maine.

American Board of Orthopaedic Surgery: Final date for filing applications for the 1952 Part II examinations is Nov. 30, 1951. Sec., Dr. Harold A. Sofield, 122 S. Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 8-12. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City.

American Board of Pediatrics: *Oral:* Buffalo, Oct. 26-28. Ex. Sec., Dr. John McK. Mitchell, 6 Cushman Rd., Rosemont, Pa.

American Board of Plastic Surgery: Denver, Oct. 27-29. Final date for filing of case reports is Aug. 30. Sec., Dr. Bradford Cannon. Office of the Board: 4647 Pershing Ave., St. Louis 8.

American Board of Preventive Medicine: *Written.* San Francisco, October 28. *Oral.* San Francisco, *October 29. Sec.*, Dr. Ernest L. Stebbins, 615 North Wolfe St., Baltimore 5.

American Board of Proctology: Philadelphia, Nov. 17-18. Sec., Dr. Louis A. Buie, 102-110 Second Ave., S.W., Rochester, Minn.

Amercian Board of Psychiatry and Neurology: *Oral* New York, Dec. 17-18. Final date for filing applications is Sept. 1. Act. Sec., Dr. David A. Boyd Jr., 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology: *Oral.* Washington, D. C., Sept. 17-22. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various centers, Oct. 1951. *Final* date for filing applications was July 1. *Written.* Various Centers. March 1952. Final date for filing application is Dec. 1, 1951. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

Board of Throacic Surgery: Written. Various parts of the country. Sept. 14, 1951. Final date for filing applications was July 15. *Oral.* St. Louis, Nov. 2. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2, Mich.

American Board of Urology: Chicago, Feb. 9-13, 1952. Final date for filing applications is Sept. 1. Sec., Dr. Harry Culver, 30 Westwood Rd., *Minneapolis 16.*

DEATHS

Hamilton, Benjamin Wallace ✠ New York; University of Pennsylvania Department of Medicine, Philadelphia, 1901; since 1936 secretary of the Medical Society of the County of New York; member of the House of Delegates of the American Medical Association from 1937 through 1940, in 1945 and 1946, and in 1949 and 1950; fellow of the New York Academy of Medicine; secretary of the Physicians Loan and Relief Fund, treasurer of the Physicians Home and trustee of the New York Physicians Mutual Aid Association; for many years affiliated with Willard Parker Hospital; served as medical editor of *New York Medicine;* died June 4, aged 73.

Cassels, Louis Raymond, Worcester, Mass.; Tufts College Medical School, Boston, 1911; police surgeon; died in Worcester City Hospital May 30, aged 65, of carcinoma of the esophagus with metastases.

Coachman, Edwin Horace ✠ Muskogee, Okla.: University of Michigan Medical School, Ann Arbor, 1926; member of the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Otolaryngology; formerly member of the school board; affiliated with Muskogee General and Oklahoma Baptist hospitals; eye, ear, nose, and throat consultant and surgeon, U. S. Veterans Administration Hospital; died May 24, aged 48.

Colby, Fred Bennett, Fitchburg, Mass.; Université de Lausanne Faculté de Médecine, Switzerland, 1937; member of the American Medical Association and the Industrial Medical Association; for many years member of the board of health; affiliated with Burbank Hospital, where he died May 24, aged 42, of coronary sclerosis.

Dinsmore, William Wert, Hartford, Conn.; Johns Hopkins University School of Medicine, Baltimore, 1907; served as associate medical director of the Travelers Insurance Company; died in Charlotte, N. C., May 17, aged 68, of cerebral hemorrhage.

Drew, Horace Rainsford, Jacksonville, Fla.; University of the South Medical Department, Sewanee, Tenn., 1901; member of the American Medical Association; past president of the Florida Medical Association and the Duval County Medical Society; veteran of the Spanish-American War; in 1916 elected to the associate staff at St. Luke's Hospital, where in 1926 he became chief of the department of medicine, and in 1933 chief of staff; died May 28, aged 74, of bronchiectasis and emphysema.

Farmer, Lucius Pierce, Stapleton, Ga.; University of Georgia School of Medicine, Augusta, 1906; served during World War I; died May 1, aged 70.

Gallion, William Earnest, Oakdale, Tenn.; Lincoln Memorial University Medical Department, Knoxville, 1909; served as mayor of Oakdale; head of the Selective Service for Morgan County during World War II; for many years company surgeon for the Southern Railroad; died in Knoxville May 26, aged 71, of cerebral hemorrhage.

Golitzin, Alexander V., Los Angeles; University of Moscow Faculty of Medicine, Russia, 1901; on the staff of Presbyterian Hospital-Olmsted Memorial; died May 4, aged 74, of hypertensive cardiovascular disease.

Greenwald, Samuel, New York; New York Homeopathic Medical College and Flower Hospital, New York, 1918; on the staff of Manhattan General Hospital, where he died June 9, aged 55, of coronary thrombosis.

Griffith, Charles Allen ✠ River Forest, Ill.; Rush Medical College, Chicago, 1908; director of the River Forest State Bank; on the executive staff at West Suburban Hospital in Oak Park, where he died May 25, aged 71, of carcinomatosis and diabetes mellitus.

Hicks, Louis Calvin, Indianapolis; Medical College of Indiana, Indianapolis, 1903; died May 28, aged 73, of rheumatic heart disease.

Holmgren, Knut David, Ottumwa, Iowa; Northwestern University Medical School, Chicago, 1910; veteran of the Spanish-American War; died in the Veterans Administration Hospital, Des Moines, May 28, aged 73, of bronchogenic carcinoma and congestive heart failure.

Howard, Everett Edmunds, Gainesville, Fla.; University of Louisville (Ky.) School of Medicine, 1913; member of the American Medical Association; served during World War I; formerly practiced in Peoria, Ill., where he was on the staffs of the Methodist and Proctor hospitals; director of student health, University of Florida Infirmary; died May 15, aged 64, of pulmonary embolus.

Jessner, Kurt Joachim, Fairfield, Maine; Ludwig-Maximilians-Universität Medizinische Fakultät, Munchen, Bavaria, Germany, 1909; member of the American Medical Association and the American Trudeau Society; assistant superintendent of the Central Maine Sanatorium; died in Waterville May 14, aged 65, of acute heart failure.

Knight, James Wesley, Madison, Wis.; Creighton University School of Medicine, Omaha, 1949; resident at St. Mary's Hospital; died May 12, aged 28, of brain tumor.

Larned, Samuel Francis, Syracuse, N. Y.; University of Pennsylvania School of Medicine, Philadelphia, 1912; member of the American Medical Association; died May 27, aged 64, of coronary occlusion.

Leonard, Lothair Lewis ✠ Asbury Park, N. J.; University of Vermont College of Medicine, Burlington, 1904; fellow of the American College of Surgeons; affiliated with Barre City Hospital in Barre, Fitkin Memorial Hospital in Neptune, and Monmouth Memorial Hospital in Long Branch; died May 17, aged 77, of coronary thrombosis.

Lewitin, Leo H., Brooklyn; Medizinische Fakultät der Universität, Wien, Austria, 1927; member of the American Medical Association; affiliated with Beth El Hospital and United Hospital, where he died March 17, aged 51, of infectious hepatitis.

Lowry, Nelson Horatio ✠ Chicago; the Hahnemann Medical College and Hospital, Chicago, 1910; fellow of the American College of Surgeons; affiliated with Illinois Masonic Hospital and Edgewater Hospital, where he died May 17, aged 66, of acute myocardial infarction.

Marchand, Malvin Carl, Oroville, Calif.; University of Kansas School of Medicine, Kansas City, 1943; member of the American Medical Association; served during World War II; died in Wells, Nev., May 19, aged 36, of injuries received in an automobile accident.

Milbee, Robert S., Sullivan, Wis.; Trinity Medical College, Toronto, Canada, 1900; died in Dalston, Ontario, Canada, March 15, aged 75, of chronic myocarditis and chronic pyelonephritis.

Reid, Rufus Tinsley, Syracuse, N. Y.; University of Virginia Department of Medicine, Charlottesville, 1911; member of the American Medical Association; died in the University Hospital May 26, aged 64, of cerebral hemorrhage.

Riess, John Turk, Red Budd, Ill.; Washington University School of Medicine, St. Louis, 1905; member of the American Medical Association; served during World War I; on the staff of St. Clement's Hospital; died June 20, aged 81, of heart disease.

Salzman, Jacob Yetter, Newark, Ohio; University of Pennsylvania School of Medicine, Philadelphia, 1909; member of th American Medical Association; died May 11, aged 71, of c cinoma.

✠ Indicates Fellow of the American Medical Association.

GOVERNMENT SERVICES

NAVY

Class of Flight Surgeons.—A naval flight surgeon class was graduated on Aug. 2 from the U. S. Naval School of Aviation Medicine, Pensacola, Fla. The class consisted of both regular and reserve medical officers. Having successfully completed 16 weeks of specialized training in the medical phase of aviation medicine, and six weeks of training in aircraft and helicopters, the graduates are now qualified for duty within the aeronautical organization of the Navy. Their primary mission will include the selection and the care of aviation personnel, the study of the aviator's operational problems, and continued research in the field of aviation medicine. Honor man in the class was Lt. (J.G.) E. J. Schoen of New York City, who compiled an academic average of 91.1 for the entire course.

Thirty student naval flight surgeons in the next class at the School of Aviation Medicine, accompanied by two faculty members, departed from Corry Field by air Aug. 13 for a four-day familiarization trip to various medical research centers of the Navy and Air Force. Visits will be made to the Human Acceleration Laboratory, Johnsville, Pa.; the Special Devices Center, Long Island; the Aero Medical Equipment Laboratory, Navy Yard, Philadelphia; and the Air Force Aero-Medical Laboratory at Wright-Patterson Field, Ohio. Field trips of this type are considered an essential part of the modern training of young naval flight surgeons, and were inaugurated by the School of Aviation Medicine in 1949.

Guest Lecturer at Naval Medical Center.—Dr. Leo H. Bartemeier, Detroit, Mich., president-elect of the American Psychiatric Association, was the guest lecturer at the Naval Medical School, Bethesda, Md., March 30. His subject was "The Attitude of the Physician."

Personals.—Rear Adm. Lamont Pugh, the Surgeon General, on June 9 addressed the annual dinner of the medical alumni of the University of Virginia at Charlottesville. Admiral Pugh departed July 6 on an inspection of Naval Medical Department facilities in the Pacific and Far East and will return to Washington by way of Alaska early in August.

Dr. Howard T. Karsner, medical research advisor to the Surgeon General, sailed for England June 29 to confer with the officer in charge of the London branch, Office of Naval Research. Dr. Karsner has also been designated the Navy delegate to the International Congress of Clinical Pathology, which is to be held in London July 16-20, where he will present a paper on "Pathology of Pulmonary Circulation." After visiting Germany in connection with research matters, he plans to return to the United States in early August.

Rear Adm. John Harper, MC, District Medical Officer, Third Naval District with headquarters in New York, retired on June 30 after 36 years of active duty. The Admiral's home address will be 4202 Yuma St., N.W., Washington, D. C.

Capt. Howard H. Montgomery, MC, USN, was placed on the retired list July 1 after 33 years of active military service. Captain Montgomery will be associated with the Blood Program of the National Red Cross in the Eastern Area Office, Alexandria, Va.

PUBLIC HEALTH SERVICE

German Physicians in Training.—Seven German physicians are in the United States for six months of advanced training under programs supervised by the Division of International Health of the Public Health Service. The training is conducted under a fellowship plan sponsored by the U. S. High Commissioner for Germany. They are Dr. Rudolf Haarstrick, preparing for a post with a child guidance clinic in the Bremen area on his return to Germany, who is studying psychiatric techniques and use of psychotherapy in child guidance clinics; Dr. Irene Haas, public health officer in Geisenheim, who is studying psychiatric techniques and use of psychotherapy in child guidance clinics; Dr. Karlheinz Hahn, public health officer in Darmstadt, who is studying public health practice and administration; Dr. Eugen Schildge, scientific assistant in the Psychiatric and Neurological Clinic, University of Freiburg, who is studying electroshock, psychotherapy, and other modern methods for treating mental illness; Dr. Gerhard Schorsch, chief medical officer of Bethel-Bielefeld Psychiatric Hospital and professor of neurology and psychiatry at the Bethel Theological College, who is studying modern psychiatric techniques, clinical and surgical, and United States methods of treating and caring for epileptics; Dr. Herbert Viefhues, psychiatrist at State Mental Hospital, Wieslock-Heidelberg, who is studying psychiatric techniques and the organization of mental health programs; and Dr. Siegfried Wagner, public health officer in Freising, who is studying public health administration.

Electrokymography.—Since radiologists and cardiologists first observed the movements of the cardiovascular silhouette on fluoroscopic screens, motions of the beating heart have been of intense interest in the study of heart disease. Researchers of Temple University School of Medicine and the Public Health Service, have developed the electrokymograph in a joint effort to discover a more adequate instrument for recording the movements of the heart and great vessels. Essential element of the device is a photomultiplier tube, which observes the movements of the heart as they appear on a fluoroscopic screen and translates the border movements and density changes to current changes. These current changes actuate a galvanometer to record a beam type of tracing on moving bromide paper. The record is called an electrokymogram. Recordings of the carotid pulse wave, the electrocardiograph, the phonocardiograph, and the electrokymograph can be made simultaneously to provide additional means for study and interpretation.

The first conference in the new field of electrokymography was held recently, and a monograph has been published by the National Heart Institute entitled "Electrokymography." The book consists of 22 scientific papers, with a discussion following each paper, and a complete bibliography. The conference was carefully planned to cover and give proper emphasis to the clinical, physiological, and technical aspects of electrokymography. A limited number of copies of the monograph may be secured without cost from the National Heart Institute, Bethesda 14, Md.

VETERANS ADMINISTRATION

Hospital News.—Dr. Gregory Pincus, Director of the Worcester Foundation for Experimental Biology, on March 2, addressed the staff at the Veterans Administration Hospital, Northport, L. I., N. Y., on the "Role of the Adrenal Cortex in Schizophrenia."——Dr. Nolan D. C. Lewis, professor of psychiatry, Columbia University, addressed the staff March 13, 1951, on the diagnosis of schizophrenia and its treatment.——Dr. Paul Hoch of the Psychiatric Institute, New York, addressed the staff on March 26 on "Personality Changes After a Lobotomy or Topectomy." On April 12 Dr. Sandor Rado, clinical professor of psychiatry at Columbia University, addressed the hospital staff on "Emergency Behavior."——Dr. H. Houston Merritt, professor of neurology at Columbia University, New York, addressed the staff April 26 on "The Use of ACTH in Nervous and Mental Diseases."

FOREIGN LETTERS

DENMARK

Correction of Speech Defects.—The publication in the near future of a textbook for teachers specializing in speech defects is just one of many signs that this particular problem is now receiving close attention in Denmark. With a population of barely four million, Denmark in 1930 had some 6,000 children suffering from defects of speech. The census yielding this figure was carried out by the Danish Department of Statistics, which undertook a survey of 451,000 children of school age. As many as 5,619 of these children (12.4%) had defects of speech. As this survey included only about 96% of all the children of school age, the above figure was raised to about 6,000. Stammering and incoordinated speech affected 2,270 of the 5,619, and stammering was found to be four times as common among boys as among girls. Among the 2,270 stammering children, there were only 89 who had received treatment at the state institute for speech defects and the majority had received no special treatment whatever.

These and many other disquieting facts emerging from this survey led the authorities to bestir themselves, and a special school with resident accommodation for 56 children and teaching facilities for 85 at a time was opened. Yet the calls made on the state institute for speech defects have continued to be so great that, as recently pointed out by Dr. Blegvad, there have been as many as 500 on the waiting list at one time. To meet what has become a veritable crisis, the authorities have developed an alternative scheme which promises well. It consists of a network throughout the country of carefully trained teachers who teach speech correction in the patient's home. The Danish Medical Association has cooperated with the Speech Teachers' Association in organizing an examining body responsible for the training of teachers specializing in speech correction. These teachers have a course of training of at least six months with an expert, spend 180 hours in the practice of teaching at the Institute, and also take part for a week in a special class. Candidates for these appointments must present evidence of an already fairly high educational standard. These teachers will to a certain extent enjoy the status of authorized masseurs, and the medical profession throughout Denmark is encouraged to make use of them. A list of them with the addresses of each is published as a supplement to a recent issue of the organ of the Danish Medical Association, *Ugeskrift for Laeger.* On this list there are between 80 and 90 names for Copenhagen and the surrounding districts alone.

Surgical Treatment of Gastric Ulcer.—At a meeting of the medical society in Copenhagen in 1944, a discussion of the comparative merits of the surgical and medical treatment of gastric and duodenal ulcer showed a definite swing in favor of the former. This trend is further illustrated by a follow-up study in 1949 of patients treated surgically during the period 1942-1945 at the Copenhagen City Hospital. The authors of this study, M. Björneboe, H. Faber, O. Mikkelsen, and E. Tobiassen, made a careful follow-up examination of 202 of the 207 patients discharged in the above-mentioned period. Cases of acute perforation were not included in this study, and the operation was usually a resection, a gastroenteroanastomosis being undertaken in only 30 cases. There were seven times as many men as women, and, while most of the patients undergoing resection were between the ages of 31 and 60, the age of most of those undergoing gastroenteroanastomosis was between 51 and 70. In nearly every case the chief indication for operation was pain. The operation mortality was 5.8% for the resections and 3.3% for the gastroenteroanastomoses. At the follow-up examination 86% of the resection cases and 83% of the gastroenteroanastomosis cases showed satisfactory recovery. Not one of the patients had died of hemorrhage or perforation after operation.

These findings are compared with those of N. B. Krarup, who in 1946 published an account of 665 patients receiving medical treatment in the period 1931-1938 at the Bispebjerg Hospital in Copenhagen. His follow-up study showed that 3% of his patients had died of hemorrhage or perforation during the observation period and that only 29% could be regarded as cured; 36% showed some improvement. Favorable as this comparison is for operative treatment, it does not tell the whole story. Since 1945 great advances have been made in the operative treatment of gastric and duodenal ulcer, owing to the availability of penicillin, to better narcosis, and to various other factors not operative before this year. In the five-year period 1946-1950, there were only 12 postoperative deaths among the 710 resection cases (1.7%) at the City Hospital, and in 1949 and 1950 there were only three postoperative deaths among fully 300 resection cases. It should also be noted that the 3% mortality from hemorrhage or perforation following conservative treatment had no counterpart in the surgically treated cases on record.

Centenary of Dr. Adolph Sell.—Born on Dec. 24, 1850, Adolph Sell came to be the founder and successful organizer of institutional treatment of epilepsy on a large and generous scale in Denmark. The son of a prosperous artisan, he qualified as a doctor in 1875, having passed his examinations with such distinction that his father financed his postgraduate tour to Vienna and Paris. On returning home, he did not pursue his further medical studies in the hospitals of Copenhagen but started general practice in the provinces, where he was so successful that he soon had to employ an assistant. By this means he was able to extend his postgraduate studies to Scotland and Germany. In the latter country he came under the influence Fr. v. Bodelswingh, who was in charge of a hospital setup consisting of many small houses surrounded by gardens; this sheltered epileptics, lunatics, and cripples, who were encouraged to live as natural a life as possible. Workshops in which these patients found employment were an innovation. At the age of 34, Sell printed a work entitled "Concerning the Significance of the Emotions as Causes of Disease." This work, submitted to the University of Copenhagen as a doctorate of medicine thesis, was rejected, presumably because it did not reflect the scientific standards of Dr. Sell's judges. It was perhaps this episode which some two years later inspired another work, in which Sell wrote among other things, "In science, psychology will appear as a new and great movement when materialism has perhaps played out its last ideal card: bacteriology."

In 1897, Sell called a meeting of his friends to discuss the creation of a colony for epileptics. An appeal was issued for funds, and a modest start was made with an epileptic picked up in the streets of Copenhagen. As the colony grew around this nucleus, Sell had to meet campaigns against him in the press, and on more than one occasion his colony was visited by inspectors looking for irregularities, which they could not find. When he died in 1921, and was succeeded by Dr. H. I. Schou, his colony had become a veritable country town with some 30 houses, a church, shop, laundry, and several hundred hospital beds. The colony was a private, self-supporting concern, to which neither the government nor the municipal authorities had contributed. In the report of this institution for the year 1948-1949, it was pointed out that Filadelfia is the only special hospital for epileptics in Denmark. While some 5% of Denmark's 14,000 epileptics are treated in Filadelfia and another 5% in various other hospitals, the remaining 90% continue to be treated at home by general practitioners.

The items in these letters are contributed by regular correspondents in the various foreign countries.

CORRESPONDENCE

DEATH FOLLOWING USE OF CURARE

To the Editor:—This letter is in reference to the case report submitted by Dr. H. Zimmerman in the June 30, 1951 issue of The Journal. This case of prolonged postoperative respiratory paralysis and death followed the administration of *d*-tubocurarine and syncurine® (decamethylene-1,10-bistrimethylammoniumdibromide) during ether anesthesia. The editorial heading of this report is entitled "Death Following Curare Administration."

On the basis of information submitted, it seems unlikely that *d*-tubocurarine is the cause of prolonged respiratory paralysis. In this instance *d*-tubocurarine and syncurine® have been loosely and inaccurately lumped together in the title. Several points should be mentioned to prevent confusion and misconception in the minds of readers. While both agents produce myoneural block and motor paralysis, *d*-tubocurarine acts in a distinctly different pharmacological manner than does syncurine.® "Decamethonium (syncurine) and *d*-tubocurarine cause neuromuscular block by fundamentally different mechanisms. Block by decamethonium is due to a persistent end-plate depolarization, analogous to an exaggeration of the normal excitant action of acetylcholine: block by curare is due to an antagonism to the normal action of acetylcholine" (Paton, W. D. M., and Zaimis, E. J.: Actions and Clinical Assessment of Drugs Which Produce Neuromuscular Block, *Lancet* **2:**568 [Nov. 18] 1950). In addition these two drugs should not be used on the same patient during surgery. "Curarization with *d*-tubocurarine almost completely abolished the response to the subsequent injections of C 10 (syncurine)" (MacFarlane, D. W., and co-workers: Evaluation of Curarizing Drugs in Man; Antagonism to Curarizing Effects of D-Tubocurarine and Decamethylene-Bis [Trimethylammonium Bromide], *J. Pharmacol. & Exper. Therap.* **99:**226 [June] 1950). The term curarization is best restricted to drugs which, like *d*-tubocurarine, act by raising the motor plate threshold to acetylcholine.

Prolonged respiratory paralysis has been mentioned in occasional cases following syncurine® (Harris, L. C., Jr., and Dripps, R. D.: The Use of Decamethonium Bromide for the Production of Muscular Relaxation, *Anesthesiol.* **11:**215 [March] 1950; Foldes, F. F., and Machaj, T. S.: Syncurine (Decamethonium-Bromide): Its Use with Pentothal-Sodium and Nitrous Oxide-Oxygen Anesthesia in Abdominal Surgery, *Anesthesiol.* **12:**366 [May] 1951). Similar cases have been revealed in personal conversations. As far as I am aware, such prolonged paralysis is not associated with the administration of *d*-tubocurarine in the dose used in this case. It would seem that adequate pulmonary ventilation should be sufficient therapy in the situation described. Although neostigmine and "tensilon" (a derivative of neostigmine) are effective pharmacological antidotes to *d*-tubocurarine, there is none at present against syncurine.® *d*-Tubocurarine is such a valuable agent that any lethal complication ascribed to it must be carefully evaluated. Unwarranted incrimination of curare as a cause of death will cause physicians to reject without proper reason an excellent adjuvant to anesthetic agents.

Buffalo 15.

ITEMIZING OF PHYSICIANS' STATEMENTS

To the Editor:—I am very interested in the statement in the Secretary's newsletter urging doctors to itemize their bills. I think that they should go still further and itemize their charges for each office visit. With this in mind some years ago we adopted what we first called a charge slip but changed to services rendered because people regarded it as an invitation to charge their accounts rather than as an itemized statement. We also felt that patients who could sign for charge purchases in the department stores could sign the slip acknowledging the receipt of the services rendered. This has enabled us to avoid many disputed accounts such as when "Veda's" husband says he gave his wife money to pay the account or when apparently they just simply forgot they were in the office. This has eliminated many unpleasant instances in our practice because the husband who says that his wife paid the account or that they just can't remember ever being to us for any services cannot deny his or his wife's signature on the slip. In addition we itemize it in detail so that a patient knows exactly what services he received and is not astonished when he receives a lump sum bill for a complete physical examination with perhaps an electrocardiograph and laboratory work. Our patients are much better satisfied with this itemized statement for each visit and no longer do they feel that the doctor is holding them up when the bill is more than three or four dollars regardless of the services rendered.

In our area, where some of the roads are good and some are bad and where travel sometimes is difficult, a number of us have quit charging by the mile and merely charge by the hour of elapsed time necessary to care for that patient. We charge from $1.50 to $3.00 fee for an office call and $3.00 to $5.00 for a home visit as a basic charge, adding in other services rendered, such as a pelvic examination or a blood count or injection of penicillin, and on long home visits or procedures that require a good deal of time we simply bill for so many hours' service. Patients are used to it and we feel that it is much fairer in that we do not penalize a person who lives on a good road by charging the same fee we would if he lived on a bad road difficult to use.

This particularly applies to night calls when a few days later all the patient remembers is that you got up at night and made a home visit and completely forgets the extra 30 to 60 minutes you had to sit around to be sure the hypodermic medication had given relief. And it also lessens the burden of explanation when the six members of a family with acute food poisoning are seen, as I did not long ago, and each member requires a different size dose of morphine, atropine and other therapy. At the time they were so sick anything seemed reasonable to them. Two weeks later when the account was paid it would have been difficult to justify the charges necessary without explaining that it involved 2½ hours at night plus two injections for each of the six members of the family. I think that elaboration on this, which I do in my classes in general practice at the University of Louisville and Meharry, would be of assistance to many young physicians starting out in practice.

MALE BREAST CARCINOMA AND ESTROGEN THERAPY

To the Editor:—In a recent report by Dr. Charles C. Higgins and me on "Bilateral Carcinoma of the Male Breast After Estrogen Therapy" (*J. A. M. A.* **146:**7 [May 5] 1951), it was inferred that the bilateral breast malignancies might be due to carcinogenic effect on male breast tissue. Through the courtesy of the Crile General Hospital, however, it has recently been learned that at autopsy the neoplasms evidenced in the bladder and in the breast were indistinguishable histologically. It is impossible, therefore, to conclude that there was a positive relationship between estrogen therapy and the breast tumors, despite the strongly suggestive evidence at the time of biopsy.

Krukenberg Tumors of Ovary.—One of the most interesting and disputed points concerning Krukenberg tumors is the mode of spread from the primary focus to the ovaries, because there is a paucity of lesions along the path between the primary lesion and the ovaries. Four possible routes are commonly listed: (1) the lymphatic route; (2) peritoneal sedimentation with implantation of cells on the ovaries; (3) hematogenous spread, and (4) direct extension to the ovaries. Most investigators support the first or second of these theories. There is little evidence to support the hematogenous route of spread. The author says that in primary tumors of the lower abdominal cavity direct extension is possible, but most of the parent tumors that yield Krukenberg tumors of the ovaries are in the upper abdomen. He gives descriptions of five cases of Krukenberg tumors observed in 10 yr. at the Cincinnati General Hospital. The average age of these patients was 41 yr. One noteworthy case occurred in a girl, 13, the earliest age at which Krukenberg tumor has ever been reported. The malignant growth apparently developed in the premenarche period, which is characterized by great endocrine activity. The course from onset of symptoms until death was only about three months. The numerous metastases found at autopsy suggest that some of the secondary growths (in liver, lung, diaphragm, calvarium, and dura mater) resulted from vascular spread. Lymphatic spread probably accounts for the involvement of the regional lymph nodes, mesentery, and retroperitoneal tissues. The mode of extension from the primary tumor in the sigmoid to the ovary was not explained. The Krukenberg tumors in all five patients were considered to be secondary to gastrointestinal neoplasms. Two patients had carcinoma in the sigmoid colon; one had carcinoma of the hepatic flexure, and two had gastric ulcerations that were probably malignant.

Tissue Culture for Differentiation Between Morphologically Identical Cells.—In a patient with pleural effusion, where other methods had failed to disclose the cause of this condition, a tissue culture of cells in the pleural fluid made possible the diagnosis of a pleural endothelioma. There was a striking variation in the appearance of the cells in tissue culture 24 and 48 hr. after culture, as compared to the cells in sections of the centrifuged fluid. Results in this case led to studies on many other pleural effusions; the histories of three such patients and of one in whom lymph node tissue was cultured are presented in this paper. Illustrations accompanying each case report show side by side the photomicrographs of the cells in the centrifuged pleural fluid (or lymph node section) and those in the tissue culture. The method at first gave some unsatisfactory results in cases of pleural effusions obtained from advanced malignant lesions in which the histopathological diagnosis was evident. This is not surprising in view of all the toxic substances present. The use of Tyrode's solution to wash away the erythrocytes greatly increased the growth. The tissue culture method is intended primarily for obscure cases, and occasionally no additional information will be gleaned from it. However, until more reliable methods are available, the authors offer tissue culture as a diagnostic aid.

Streptomycin in Tuberculous Pericarditis.—Carroll analyzes the course of untreated tuberculous pericarditis in 71 patients and reports the results of streptomycin therapy in five additional patients. Of the untreated patients, 40.5% died of widespread tuberculosis, 8.5% died of cardiac failure, and 19.5% survived for five years or more. The fate of the others is unknown. Only three of the 21 patients alive five years or more after the original pericarditis had any signs or symptoms attributable to previous tuberculous pericarditis. Of the five streptomycin-treated patients, one became asymptomatic after a four-month course of therapy, one who received streptomycin for only two weeks succumbed to widely disseminated tuberculosis, and three showed signs of constrictive pericarditis after the systemic disease was brought under control. In these three patients early corrective surgical intervention was made possible by streptomycin therapy. Important factors in the recovery of these patients were the early institution of therapy and the continuation of bed rest and streptomycin therapy for long periods after surgical correction of constrictive pericarditis. The principal value of streptomycin in these cases lay in its ability, in adequate dosage, to prevent dissemination of tuberculosis.

The Association library lends periodicals to members of the Association and to individual subscribers in Continental United States and Canada for a period of five days. Three journals may be borrowed at a time. Periodicals are available from 1940 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Effects of Cortisone and ACTH on Acute Phase of Rheumatic Fever. A. R. Barnes.—p. 770.

Effect of Angiocardiography on Heart.—Six patients studied by angiocardiography or aortography were checked by a direct-writer type of electrocardiograph during the procedure. The diseases found consisted of pulmonary stenosis, coarctation of the aorta, aneurysm of the ascending aorta, ventricular septal defect (two cases), and atrial septal defect associated with complete transposition of the great vessels. Immediate ischemic changes, as evidenced by T-wave inversion, were induced by rapid injection of 75% sodium iodomethamate (neo-iopax®). Irritable ventricular foci with frequent and prolonged bursts of ventricular tachycardia were frequently produced. Both events are delayed in onset and may persist for at least one-half hour after the injection of sodium iodomethamate. Premedication with adequate amounts of quinidine or procaine amide appeared to lessen the hazard of the procedure. Retrograde aortography when indicated may not present so great a cardiac risk as angiocardiography, probably because less of the contrast medium contacts the myocardium. It is concluded that direct-writer continuous electrocardiographic observation during angiocardiography should be maintained at all times. It is cautioned that the procedure is diagnostic and not therapeutic. As angiocardiography is associated with a 0.4% to 1.0% mortality, the procedure should be surrounded by all possible safeguards.

Corticotrophin (ACTH) and Chronic Bronchial Asthma.—This is a report on the use of corticotrophin (ACTH) in the management of 20 patients with severe bronchial asthma who had been subject to asthmatic attacks for one to 30 yr. Most of these patients were in status asthmaticus, and all had shown poor response to intensive conservative treatment. An initial dose of 40 mg. was followed by 40 mg. six hours later; then 20 mg. was administered every six hours until maximum benefit had been observed for two days. The time interval was then increased to every eight hours for one to two days and from the fifth day on to every 12 hr. If adequate eosinopenia did not develop after 100 mg. had been given, the dosage schedule was increased. The total dose of a single course of therapy varied from 240 mg. to 900 mg., and the duration of treatment from two and a half days to 19 days. Two patients required three courses and three patients two courses of therapy. All but three of 27 courses of therapy were followed by partial or complete remissions. One patient did not respond satisfactorily to two courses of corticotrophin and one course of cortisone. Eighteen courses of therapy were followed by complete remissions lasting from nine days to seven months. In evaluating the continued therapeutic effect, the authors arbitrarily considered remissions that lasted less than one week as failures, those from one to two weeks as fair, those from two to four weeks as good, and those longer than four weeks as excellent. With this grading, the continued therapeutic effects must be regarded as failures in three cases, as fair in eight, as good in 10, and as excellent in six. Repeated, short intensive courses of therapy are more effective in long-term management than are attempts to prolong the initial remission with daily maintenance therapy.

*Cerebral Blood Flow and Metabolism in Psychoses of Senility. F. A. Freyham, R. B. Woodford and S. S. Kety.—p. 449.

Psychoses of Senility.—The 10 patients chosen for this study represent two types of organic disturbances: (1) psychosis with cerebral arteriosclerosis (six cases) and (2) senile psychosis (four cases). Differentiation between these two entities is difficult. The diagnosis of senile psychosis is usually based on certain behavioral characteristics that occur in the absence of noticeable vascular pathology, but, in cases of senile psychosis, it is difficult to exclude degenerative processes of the cerebral blood vessels. The case histories indicate that the 10 cases have in common progressive behavioral deterioration and psychotic changes of personality associated with senile organic disturbances. Cerebral blood flow was determined by the nitrous oxide method, with the use of a special gas mixture. Mean arterial blood pressure was obtained by means of a damped mercury manometer attached to a needle in the femoral artery. The authors calculated the cerebral metabolic rate in terms of cerebral oxygen consumption by multiplying the difference in the oxygen content between the arterial and internal jugular blood by the cerebral blood flow. In calculating the cerebrovascular resistance, a measure of the caliber of the cerebral vessels, the mean arterial blood pressure was divided by the cerebral blood flow. The data obtained strongly suggest that the senile psychoses are the result of a significant reduction in cerebral oxygen utilization on the basis of an increased cerebrovascular resistance and its resultant reduction in blood flow through the brain. There is no essential difference in this respect between the two clinical classifications of "psychosis with cerebral arteriosclerosis" and "senile psychosis." A comparable series of elderly persons without psychosis should be studied, for only in this manner could it be demonstrated that the psychosis depends on circulatory and metabolic changes.

Hydronephrosis in Infants and Children.—The occurrence of hydronephrosis is reported in 828 infants and children. The condition was discovered at necropsy in 316 cases and was disclosed by urologic investigation during life in 512 patients. Bilateral hydronephrosis was observed in 359 cases (43.4%). Of the 512 patients, 49 refused treatment or did not receive it. Of those treated, 82 died and 84 were cured, i. e., urinary stasis was relieved, the urine sterilized, and renal function adequate to support life for a reasonable number of years was achieved. There was improvement in 169 patients. Thirty-seven in whom stasis persisted were therapeutic failures and the others were lost to observation. Hydronephrosis is the commonest abdominal tumor of childhood at which time it results oftenest from congenital causes. In rare instances the obstruction is acquired as in urinary calculus disease or spinal injury. The pathological changes are fundamentally those of renal destruction and are anatomically characterized by pelvicalyceal dilatation, parenchymal thinning, sclerosis, and destruction of secretory elements. The indications for complete urologic examination of children with hydronephrosis are many, but persistent or acute pyuria, pain, or a mass in the loin or abdomen, hematuria, and reflex vesical disturbances are the usual symptoms. The diagnosis is readily suggested by excretory urographic study and can be established by satisfactory retrograde and preferably bilateral pyelography. Treatment is surgical when indicated, but occasionally conservative therapy by instrumental dilation may be successful. In most cases operation is necessary. It may not always be radical, yet in a third to a half of the children in whom hydronephrosis has been clinically recognized, the severity of the renal damage necessitates total nephrectomy. With early diagnosis and proper treatment, most of these kidneys as well as the lives of many patients should be saved.

Mortality Rate in Transurethral Prostatic Resection.—Free hemoglobin formed in the bladder by contact between blood and the plain water used as irrigating fluid during transurethral prostatic resection may be driven into the circulation when large prostatic veins are opened. When this free hemoglobin reaches the kidneys, renal vasospasm results and may lead to severe or fatal renal damage, particularly in the presence of rapid loss of blood, hypotension, bacteremia, or preexisting renal damage. This reaction is prevented by the use of an isotonic irrigating solution, such as dextrose, aminoacetic acid, or mannitol, and the morbidity and mortality rates of transurethral resection of the prostate are consequently lowered. In a series of 1,000 consecutive cases in which transurethral resection was done by the author with dextrose and aminoacetic acid as the irrigating solutions, the surgical mortality rate was 0.6%; this is about as low as can be expected in surgical interventions on elderly men. The operative mortality rate was 5.3% in 2,435 open enucleations from many smaller series reported in the literature between 1945 and 1950. It seems reasonable to suppose that the difference between the mortality rate in the author's series and that of other series is due to the use of isotonic irrigating fluid. A mortality rate lower than that ordinarily attained by many experts with the open operations may be achieved in transurethral resection with the use of nonhemolytic solutions on patients who are, on the average, very poor risks.

Infantile Cortical Hyperostosis.—It has been recognized that infantile cortical hyperostosis may be the result of poisoning with vitamin A. This paper presents the histories of four such children who were seen during the past three years at the Hospital for Children at the University of Oregon, Portland, Ore. All the children had received vitamin supplements. None were breastfed. Two patients showed changes in the ilium not previously described. Clinical symptoms are of little differential value, since the general irritability and upset feeding habits are present in metabolic disease, infectious diseases, and hypertrophic pyloric stenosis. Tender, soft tissue swelling over the mandibles, scapulas, clavicles or extremities requires roentgenographic examination of the underlying bone. Roentgenographic appearance is the best basis for early diagnosis. Subperiosteal proliferation of the mandible, ribs, clavicles, long bones, and scapulas is typical. Long bone changes are characteristically confined to midshaft and do not extend to the epiphyses. Early, the subperiosteal calcific density is homogenous and approximates the density of cortical bone. Later, calcification becomes coarse and trabeculated and decreases in density and extent. A history of concentrated fish liver oil intake above normal requirements is the clue to correct diagnosis. This disorder may be mistaken for syphilitic periostitis, osteomyelitis, and even for bone cancer, as in one of the cases described here.

Action of Alloxan on Hypoglycemia.—A female infant aged 8 months with severe spontaneous hypoglycemia and associated convulsions was not significantly improved with epinephrine injections, and a subtotal pancreatectomy gave only temporary relief. Intravenous injections of alloxan monohydrate were then given for 20 days. Initially, the patient was given 25 mg. per kilogram of body weight, but this dose was increased to 60 mg. per kilogram by the end of this injection period. The intravenous injections of alloxan produced no untoward systemic effects, but the veins were rapidly sclerosed locally. The child had no convulsions during the 20 days she was receiving alloxan and remained well for five days after this treatment but had severe generalized convulsions on the sixth and again on the ninth day after alloxan was discontinued. Consequently, a second course of alloxan treatment was started immediately. The dosage was eventually increased to 75 mg. per kilogram of body weight. After eight days of treatment there was no definite improvement in her blood sugar values, and all veins that could be used were sclerosed. As a final attempt large doses of alloxan (150 mg. per kilogram of body weight as a 0.6% solution) were given for three days by subcutaneous route. This method of administration proved painful, and the fluid was absorbed slowly and produced hard, indurated areas that occasionally broke down. The clinical course after alloxan treatment was uneventful. The patient remained well and free from convulsions. The blood sugar values showed improvement, and the glucose tolerance also was improved. The response noted in this child with alloxan therapy indicates that the initial dose should be approximately 55 mg. per kilogram of body weight until a mild hyperglycemia is produced. Fourteen months after the last injection of alloxan the child had remained free of convulsions and her social developmental age was considered to be within normal limits. Blood sugar values obtained during the 14-month interval were improved over the prealloxan picture, although values below the normal fasting level have been observed.

Endocardial Sclerosis.—Sudden death is reported in six infants between the ages of 3 days and 20 months, in whom hypertrophy of the left side of the heart, thickening, opacity, and milky discoloration of the endocardium and varying degrees of distortion of the cardiac valves were outstanding features at necropsy. The ages of these patients and the lack of evidence of postnatal infection or inflammation in the history, physical examination, and necropsy suggest that the lesions observed were the result of an antenatal process, the nature of which is not definitely established. Microscopic examination of the affected areas showed dense collagenous-fibrous tissue in the place of normal endocardium, obviously a change of considerable duration and possibly referable to the time of the actual formation of the heart. The syndrome was characterized by radiologically demonstrable cardiac enlargement, nondiagnostic murmurs, and sudden death in infancy. The older concept of an inflammatory pathogenesis of so-called fetal endocarditis is rejected in favor of developmental origin of the lesions. The more recently proposed term "endocardial sclerosis" is preferred by the authors. As a group the cases reported may represent a distinct species of congenital cardiac malformation, perhaps analogous to the group of transpositions of the great arterial trunks of the heart. Cases of left-sided endocardial thickening with valve deformity, such as reported here, may find a theoretical common denominator in terms of segmental variation in tissue differentiation. Extensive fibroelastosis in the truncus segment of the embryo produces normally differentiated aortic and pulmonic trunks. Similar but less pronounced fibroelastosis in a portion of the bulboventricular loop would represent heterotopia resulting in the lesions of endocardial sclerosis.

Triscuspid Atresia.—Tricuspid atresia is one of the cyanotic forms of congenital heart disease that may be alleviated if additional pulmonary blood flow is provided. Because the antemortem diagnosis of tricuspid atresia may lead to corrective cardiac surgery, the criteria for diagnosis must be clearly delineated. Persistent pronounced cyanosis, a concave left upper cardiac border in the anterior-posterior roentgenogram, absence of right ventricular enlargement in the left anterior-oblique projection, and the substantiating electrocardiographic picture of left axis deviation have been the generally accepted diagnostic criteria. Awareness of their limitations is desirable. Three cases of tricuspid atresia in infants aged 5 weeks, 4 months, and 6 months, respectively, are reported. Pott's operation was performed on one of the three patients at the age of 1 yr. and was followed by pronounced and lasting improvement. The patient is alive and relatively well at the age of 3. The two other cases were fatal, one of which was characterized by the absence of left axis deviation on the electrocardiogram and the presence of roentgenologic signs apparently consistent with an increase in the size of the right ventricle. Angiocardiographic studies, however, were suggestive of tricuspid atresia. Although in most cases the classic findings will lead to an unequivocal diagnosis, it must be recognized that the combination of a congenital cardiac anomaly of the cyanotic type with left axis deviation is by no means pathognomonic of tricuspid atresia. Conversely, the absence of left axis deviation on the electrocardiogram does not exclude the possibility of this disease. Similarly, roentgenologic studies need not be conclusive. The presence of an underdeveloped right ventricle may be obscured in the conventional examination. In atypical cases angiocardiography may be the only method of establishing the diagnosis conclusively. For the intensely cyanotic young infant whose immediate prognosis is poor, special diagnostic procedures should be performed, whenever conventional methods have failed to clarify the nature of the anomaly. Although some risk is attached to these procedures, the danger may be far less than in conservative management of such cases.

Evaluation of Parenteral Chloramphenicol Therapy.—The clinical and therapeutic effects and the serum levels of chloramphenicol (chloromycetin®) were studied in 38 patients with various infections to whom this drug was administered intravenously and/or intramuscularly. The usual dose employed intravenously was 0.5 to 1 gm. of chloramphenicol in 2 to 4 cc. of acetyl dimethylamine added to 250 to 500 cc. of dextrose or isotonic sodium chloride solution and given at six-hour intervals. The same initial dose of chloramphenicol dissolved in acetyl dimethylamine but not diluted in dextrose or isotonic sodium chloride solution, with additional maintenance doses of 250 mg. to 0.5 gm. of chloramphenicol at six-hour intervals, was given intramuscularly. Results showed that chloramphenicol when dissolved in acetyl dimethylamine may be safely administered intravenously or intramuscularly. As yet, no ill effects by these parenteral routes, such as allergic or toxic reactions, were observed. There were no signs of bone depression or neutropenic reactions or evidences of hepatic or renal damage. Chloramphenicol was administered to some of the patients for three weeks by intramuscular route with no evidence of sensitization or toxicity developing in any during that period. Infants and aged persons as well as young adults were among the patients treated. This is the first reported instance in which chloramphenicol dissolved in acetyl dimethylamine was employed for intramuscular use. In most of the patients the response to intramuscularly administered chloramphenicol was satisfyingly prompt. The injection should be made deep in the muscle, so that local tissue necrosis will not occur and also so that discomfort at the time and site of injection will be reduced. Both the oral and the intramuscular routes showed the same phenomenon, in which the blood levels rose to their maximum concentrations up to the sixth hour after administration and then fell off sharply in the next two hours. When the maintenance dose, usually 250 mg., given either orally or intramuscularly, was repeated at six-hour intervals, a sustained level of 5 γ per cubic centimeter could be maintained day after day. Longer intervals between injections resulted in a decrease in concentration below that theoretically desirable.

Bilateral Femoral Vein Ligation for Prevention of Pulmonary Embolism.—In 1,650 autopsies, 167 cases of pulmonary embolism were discovered, an incidence of 10.3%. The embolism was considered of sufficient magnitude to have at least contributed to the fatality in 87 patients. This would indicate that in roughly 5% of the cases in which autopsy was performed, pulmonary embolism could be considered as a major factor in the cause of death. The highest incidence (24 of the major embolic cases) was observed in the orthopedic department, so a group of cases from this department was selected for evaluation of bilateral superficial femoral vein ligation in preventing pulmonary embolism. In all, 100 patients with recent fracture of the femur were studied, of whom 50 were subjected to ligation and 50 were not. It appeared that in aged patients with fracture of the neck of the femur, bilateral superficial femoral vein ligation, in itself, does not lower the mortality rate due to pulmonary embolism nor the incidence of nonfatal pulmonic episodes. The ligation in such patients is frequently followed by thrombosis arising in the proximal femoral vein compartment, and pulmonary embolism is a common occurrence.

"Growing Pains": Limb Pains in Children.—Limb pains occur oftener in children than in adults, and so such pains have been dubbed "growing pains." Yet the ages 8 to 12, when the pains are commonest, are one of the "filling-out" intervals between two periods of rapid growth. A further criticism of the term is that the commoner sites of pain do not correspond to the sites of maximal growth. Moreover, it appears improbable that pains as intermittent as those described could be related to a process as gradual as that of growth. Naish and Apley questioned 721 children in routine examinations at school clinics regarding the occurrence of limb pains. Thirty (4.2%) of the children were found to have persistent nonarthritic limb pains. By comparison with controls, a family history of rheumatic disorders was found to be significantly commoner in children with such pains. Minor emotional disturbances also seemed common. Most of the children with limb pains fell into one of two groups. First, diurnal fatigue pains occurred in children in association with exertion, fatigue, and postural defects. In this group emotional disturbances were common, and there was a family history of rheumatic disorders. Second, paroxysmal nocturnal pains occurred in children who were more stable emotionally but who came from families in whom similar pains were common. This familiar occurrence and the fact that cold and damp conditions seemed to play a part suggest the possibility of an abnormal familial response to atmospheric conditions, but positive evidence for this is lacking. These studies suggest that limb pains, even when manifest organic disease has been excluded, comprise more than one single clinical entity. Psychic factors play an important part, but this is only one facet of the problem. Data are required regarding familial responses to atmospheric changes, and the familial relationship, if any, between pain and psychic aberrations. The term "growing pains" should be discarded, since the pains have no demonstrable connection with growth.

Oil Aspiration Pneumonia in Infancy.—This paper reports the case of a boy who was hospitalized at 8½ months with a complaint of weight loss, stertorous breathing, and hyperhidrosis for one month. He was successfully breast-fed for three months and when weaned was given a half-cream proprietary dried milk preparation in six and then five feedings per day. He was also given one teaspoonful of cod liver oil daily and unsweetened orange juice, but the diet was seemingly inadequate. He became constipated and from the age of 6 months until his admission to hospital was given three teaspoonfuls of liquid petrolatum (medicinal paraffin) daily. From 7½ months his mother noticed that he had rapid, noisy breathing, especially at night. A roentgenogram of the chest revealed diffuse parenchymal inflammatory changes of a pneumonic type, but the possibility of lipid pneumonia was not considered until the post-morten examination, at which a thin film of oil was found covering the mucous surfaces of the trachea and bronchi. From chemical and histological examinations it became clear that liquid petrolatum was the oil mainly responsible for the pneumonia, but the finding in the air passages of large oil droplets staining with osmic acid suggests that a terminal aspiration of food fats may have occurred. The literature furnishes no information on the relative dangers of nasal or oral administration of medicinal paraffin to infants. In many cases both routes have been involved. However, it is clear from cases of lipid pneumonia like the one here reported, in which nose drops were not used, that oral administration alone may result in aspiration. A healthy infant may be able to take liquid petrolatum by mouth without harmful effects, but its use is contraindicated in infants who resist oil administration, who are suffering from dysphagia or cough, or who are debilitated as the result of illness or congenital deformity. These warnings also apply to the administration of cod liver oil.

Hypothermia in Heart Surgery.—The difficulties and obstacles of intracardiac surgery are discussed, and means of overcoming them are evaluated. The devices designed to act as artificial hearts provide the oxygen-poor blood with oxygen and maintain systemic circulation, at least the portion supplying the brain. These apparatuses are complicated and in consequence are subject to disturbances that may quickly endanger life. Boerema and associates therefore decided to eliminate the need for an artificial heart by reducing as much as possible the amount of oxygen required by the brain and other tissues. They accomplished this by reducing the body temperature. They describe their own studies on animals and mention the efforts made by others to accomplish cooling. They found that by considerable cooling, the metabolic rate in animals dropped so far that the brain could dispense with the circulation of the blood for a period three times as long as is normally possible. There was ample time to open the heart, which had been almost drained of blood by clamping the venae cavae, and for performance of an intracardial operation under direct vision. This method may eliminate the necessity for an artificial heart in cardiac surgery.

*Nitrogen Mustard in Treatment of Hodgkin's Disease, Lymphosarcoma, Leukemia and Similar Diseases. J. de Lorenzo and P. Jannini.—p. 141.

Nitrogen Mustard in Hodgkin's Disease.—The authors administered nitrogen mustard to six patients with Hodgkin's disease, lymphosarcoma or myxoma. Intravenous injections of 0.1 mg. of nitrogen mustard per kilogram of body weight up to a total daily dose of 5 and 6 mg. were given either daily or every other day for a series of two to six injections. The three patients with Hodgkin's disease were in an advanced stage when the treatment started. The first patient has been under observation for three years. The disease was resistant to roentgen treatment, but after three series of nitrogen mustard treatments at intervals of several months, the patient was able to return to work. Several months after apparent cure his symptoms recurred intermittently, so that he required further treatment. A total of six series of injections was given in three years. He is now relatively well, his blood is normal, and he is still working. The other two patients were very ill when the treatment was started. They died from agranulocytosis after having received only two and five injections. One patient with lymphosarcoma of the pharynx and neck,

---

An asterisk (*) before a title indicates that the article is abstracted. Single case reports and trials of new drugs are usually omitted.

who had not responded to roentgen treatment, improved after each of two series of injections and returned to work. He subsequently died suddenly from acute hemorrhage from the tumor. In the other patient with lymphosarcoma spectacular improvement occurred after a series of four injections. The patient was able to resume work, and is still working and in good general condition one year and nine months after treatment. The patient with roentgen-resistant myxosarcoma of the psoas muscle with pleuropulmonary metastases and with clinical symptoms and blood changes of angina agranulocytotica had a series of treatments in a week. Two weeks after treatment he died in collapse. In all the aforementioned cases fever and malaise disappeared and the tumors rapidly regressed after treatment.

House to House Spread of Tuberculosis.—This investigation was induced by the observation that many tuberculous patients lived next door to one another. It was based on statistics for Northampton, which is comparable in standard of living and population structure to other towns of the same size in England and Wales. Over a period of 28 years (1921-1948) tuberculosis was reported from 2,871 houses. Approximately 20% of the affected houses were grouped by two or three. The number of next-door pairs of houses that would have been affected in a random distribution of the cases was calculated by formulas from the mathematical theory of the random distribution of points in one dimension. Allowance was made for differences between good, fair, and poor housing, but only the interrelationships of houses on the same side of a street were taken into consideration. The number of affected persons in houses next door to one another was found to be significantly greater than the number to be expected had the cases been randomly distributed. It was also found that for any period up to 12 years the number of pairs of cases reported from the same house and from next-door houses was significantly in excess of the number to be expected from pure chance.

Cortisone and Skin Grafts.—The daily subcutaneous administration of 10 mg. of cortisone acetate to adult rabbits of either sex weakens the primary healing of autogenous or homologous grafts, delays their vascularization and the cellular proliferation consequent on it, and retards their histological reorganization. The contracture of graft-bearing areas is retarded by cortisone treatment but proceeds eventually to the same degree as in untreated animals. The administration of cortisone lengthens the life of skin homografts in rabbits by a factor of three or four. This is thought to be due partly to a nonspecific reduction of the graft's ability to elicit an immune response but mainly to the reduction of the response itself. The survival time of homografts in rabbits already made specifically immune by an earlier grafting from the same donor is little lengthened by the administration of cortisone. It is therefore concluded that cortisone affects the systemic development rather than the local fulfilment of the immune response.

Causes of Post-Gastrectomy Syndrome.—To determine the cause of the unpleasant symptoms that sometimes follow partial gastrectomy, Butler and Capper studied 79 patients with post-gastrectomy syndrome after the Polya type of gastric resection. They found that several different mechanisms were involved. Distension of the jejunum with a balloon reproduced the sensation of central abdominal fulness but not the vasomotor effects, namely, the feeling of warmth, sweating, tachycardia, and palpitation, which are even more distressing. These were reproduced when a bag containing an amount of mercury equal in weight to that of a heavy meal was inserted into the remnant of the stomach, and they were relieved when the patient was shifted from the upright to the supine position. The shift in position did not, however, abolish the sensation of fulness due to the balloon. Splanchnic block abolished both types of symptom, suggesting that they are mediated by the sympathetic rather than by the vagus nerves. Radiologic examination following a barium meal demonstrated that inert substances such as barium are capable of producing the syndrome, that symptoms may occur before jejunal filling has begun, that there is no significant difference in the incidence of rapid or delayed emptying or afferent-loop filling in patients with or without the syndrome, and that there is greater descent of the gastric stoma in changing from the supine to the erect position in patients with the syndrome than in those without. Glucose tolerance tests showed no significant differences in the blood sugar curve of those with and without the early syndrome, so that hypoglycemia cannot be regarded as a cause of these symptoms.

*Behavior of Hydrochloric Acid Secretion in Cardiopathies. D. Furbetta, V. Giunti and P. Solinas.—p. 277.
Roentgenologic Aspect of Traube's Tympany. W. Telò.—p. 287.

Hydrochloric Acid Secretion in Cardiopathy.—The hydrochloric acid secretion of the stomach was studied in 117 patients with cardiopathy, 41 with compensated mitral and 24 with compensated aortic lesions, 18 with compensated hypertension, 21 with decompensated cardiopathy, and 13 with various forms of compensated cardiopathy. The gastric juice was examined before and after meals; histamine stimulation was employed in patients with achlorhydria. The hydrochloric acid secretion was below normal in 67% of the patients, normal in 26.4%, and above normal in 6.6%. Two examinations of the gastric juice at intervals of 15 days showed a definite drop of the hydrochloric acid secretion in two patients in whom the cardiopathy continued to develop during the period of observation. Thus cardiopathy seems to be associated with hyposecretion of hydrochloric acid. It is suggested that this anomaly is caused by changes in the circulatory dynamics of the gastric secretive apparatus. It may be a manifestation of hypoxemia of the stomach tissues.

Gastric Function After Gastric Instillation of Meal.—To determine the effect of afferent impulses from the mouth, pharynx, and esophagus set up during the swallowing of a meal on subsequent gastric response, experiments were performed in which the emptying and secretion of the stomach after a swallowed meal were compared with that after a meal introduced into the stomach through a tube. Observations on eight normal subjects indicated that the emptying process was not significantly influenced by the test procedure. It was concluded that the absence of afferent impulses from the mouth, pharynx, and esophagus did not modify gastric digestive activity in response to the pectin meal.

Erythema Multiforme Exudativum (Stevens-Johnson Syndrome).—Ashby and Lazar point out that the eruptive fever, which, according to the description of Stevens and Johnson in 1922, is characterized by pleomorphous rash, ulceration of the mouth, purulent conjunctivitis, and severe constitutional symptoms, was not really a new entity, having been described by Hebra in 1860 under the name erythema multiforme exudativum. Other names under which reports of cases indistinguishable from Stevens-Johnson syndrome have been published are "ectodermosis erosiva pluriorificalis" and "dermostomatitis." More recently it has been shown that the skin need not necessarily be affected and that abacterial pneumonia may be a feature. The histories of four patients with this disorder, observed by Ashby and Lazar, are presented, and an additional 77 cases from the literature are analyzed. Sixty-nine of the 81 patients were less than 30 years old. The syndrome is rare after 50. The disease is much more frequent in men than in women (66 men and 15 women in this group). All patients had lesions of the mouth or lips. Conjunctivitis was present in 74 cases. Seven patients had corneal involvement; six of these were left with permanent visual defect (five totally blind). Of the 66 males, 30 had penile lesions and seven had urethral discharge. Skin eruptions were seen in 67 patients. The authors raise the question whether the Stevens-Johnson syndrome is a specific infectious fever with a single causal agent, possibly virus, or a nonspecific syndrome that may be produced by various noxious agents as a form of allergy. Obviously, it is an anachronism to suggest that cases first described in 1922, much less those described in 1860, were caused by sulfonamides. If aureomycin proves to be a specific cure for Stevens-Johnson syndrome, the theory of an infective etiology will be strengthened. The clinical difference between the severe eruptive fever with stomatitis and ophthalmia described by Stevens and Johnson and the mild skin disease of Hebra is so distinct that their relationship is questionable, but if the conditions are variants of the same disease, it is suggested that the suffix "Stevens-Johnson" be attached to the severe form of erythema multiforme and the suffix "Hebra" to the mild form.

*Functions of Adrenal Cortex in Myxedema. F. A. de la Balze, F. C. Arrillaga and R. E. Mancini.—p. 25.

Functions of Adrenal Cortex in Myxedema.—Tests to ascertain certain functions of the adrenal cortex were performed in 11 patients with myxedema and spontaneous primary thyroid insufficiency. The patients were observed for two to 10 months. Before treatment the metabolism of water and electrolytes was normal, as was proved by the Robinson-Power-Kepler test. Elimination of 17-ketosteroids was greatly diminished in all patients. The number of circulating eosinophils was above normal, as compared to that in 102 normal persons. The subcutaneous injection of 0.3 cc. of a 1:1000 epinephrine hydrochloride solution caused a fall in the circulating eosinophils in seven out of the 11 patients. The fall in these patients was not so great as normal. The intravenous epinephrine test was done on three of these patients, and the results were similar to those of the subcutaneous test. In these three patients, eosinopenia was also induced by an intramuscular injection of (1) 20 mg. of corticotrophin, (2) 100 mg. of cortisone and (3) a subcutaneous injection of 15 mg. of methamphetamine hydrochloride (methedrine®). The results of the three tests agreed with those of the postepinephrine eosinopenia test, showing dysfunction of the glycogenic corticoids. The treatment consisted of administration of a daily dose of 0.10 to 0.25 gm. of powder of desiccated thyroid, until normal thyroid function returned. After treatment the postepinephrine drop in eosinophils was as great as normal in the seven patients in whom it was abnormal before treatment. The urinary 17-ketosteroids returned to normal values in one out of three patients in whom the determination after treatment was made. The authors believe that the functional corticoadrenal disorders that occur in the course of myxedema are due to a hypophysial disturbance that results in a diminished secretion of corticotrophin and of other corticoadrenal hormones.

Three Types of Pneumonia Treatment.—*In 419 cases,* Nielsen and Søttrup found that combined sulfonamide and penicillin treatment of pneumonia showed no advantages over sulfonamide treatment or penicillin treatment alone and that penicillin cannot be regarded as superior to sulfonamides in therapeutic effect. The Central Hospital in Randers, however, has adopted antibiotics (at present dipenicillin) as the standard method of treatment of pneumonia because of increasingly numerous reports of more or less marked side-effects associated with sulfonamides.

*Diagnosis of Chronic Cor Pulmonale. L. Herve, M. Brodsky, F. Duran and others.—p. 197.

Diagnosis of Chronic Cor Pulmonale.—Herve and collaborators found chronic cor pulmonale in 32 patients out of a group of 116 adults with chronic bronchopulmonary diseases. The disease was secondary to chronic bronchitis in 11 cases, to bronchiectasis in 11 cases, and to silicosis, bronchial asthma, fibrous pulmonary tuberculosis, or emphysema in the remaining 10 cases. It was of the pure form in 10 of these cases and associated with coronary disease, arterial hypertension, or arteriosclerosis in 22. One case of a latent subclinical form was also encountered. The pure form developed in persons of an average age of 44. The duration of the bronchopulmonary disease, up to the appearance of the cardiac symptoms, was between one and two years, and right ventricular hypertrophy developed quickly. In three patients the cardiac disease assumed a malignant form comparable to the malignant form of arterial hypertension; in seven it was subacute. The associated form of the disease developed in patients of an average age of 63. The bronchopulmonary disease was of long duration, right ventricular hypertrophy developed slowly, and the symptoms of chronic cor pulmonale were often masked by those of the coronary or vascular disease. The latent form is extremely rare. The diagnosis of chronic cor pulmonale was mainly based on (1) the electrocardiographic changes, which showed preponderance of the right ventricle, (2) the results of cardiac catheterization, which showed pulmonary arterial hypertension, and (3) the results of the tests for anoxemia, either compensated or decompensated. In the differential diagnosis the following conditions must be considered: congenital heart diseases causing cyanosis, valvular defects, insufficiency of the right ventricle secondary to arterial diseases, and constrictive pericarditis.

Study of Behavior of Chronic Progressive Polyarthritis and Ankylopoietic Spondylarthritis Treated with Cortisone. J. Forestier, A. Certonciny, F. Jacqueline and J. Saint-Marc.—p. 167.
Cortisone and Corticotrophin (ACTH) in Rheumatology: Results of Treatment in 58 Cases. S. de Sèze, J. Robin, P. Ordonneau and others.—p. 177.
*Undesirable Thromboembolic Effects of Treatment with Cortisone and *Corticotrophin (Pituitary Adrenocorticotropic* Hormone). F. Coste, P. Galmiche, B. Piguet and others.—p. 189.

Thromboembolic Episodes in Patients Treated with Cortisone and Corticotrophin.—The occurrence of thromboembolic complications during the course of treatment with cortisone or corticotrophin (ACTH) is reported in five patients between the ages of 21 and 69, one with polyarticular gout, one with rheumatic carditis, one with multiple myeloma, one with chronic progressive polyarthritis, and one with gouty hydrarthrosis of the knee. The thromboembolic episodes observed were a flare-up of coronary artery disease in the first patient, pulmonary infarction in the second patient, and phlebitis in the three other patients. Considerable shortening of the coagulation time was observed in two of the patients with phlebitis, and one of them showed persistent reduction of the coagulation time in spite of treatment with heparin. Similar observations were reported by Cosgriff and co-workers, who stated that the mechanism of this change in blood coagulation is not clear. Coste and coworkers agree with this statement but believe that an increase in the number of blood platelets (335,000 per cubic millimeter), which was observed in several of their cases, may play a part in the disturbance of the blood coagulation. Studies are to be continued in this respect. It seems that the higher the dose of the drug, the greater the risk of thromboembolic complications associated with the treatment of patients with cortisone or corticotrophin, particularly when predisposing factors, such as prolonged bed rest, postoperative shortening of the coagulation time, or cardiac failure are present. Treatment with cortisone or corticotrophin combined with prophylactic treatment with anticoagulants is indicated.

*Clinical Contribution to New Treatment of Rheumatic Diseases with Extracts of Total Adrenal Cortex Combined with Vitamin C. D. Bassi and G. Zotti.—p. 162.

Effects of Nitrogen Mustard on Tuberculous Lymphadenitis.—Five patients with tuberculous lymphadenitis of hyperplastic type were given methyl-bis (beta-chloroethyl) amine hydrochloride (nitrogen mustard) injections in doses of 5 mg. every other day, with a total of six to eight injections. The diagnosis was established in four of the five patients by lymph node biopsy. Pronounced enlargement of the axillary and laterocervical lymph nodes was observed in three patients, and considerable swelling of the mediastinal lymph nodes in the two others. Previous treatment with calcium compounds, vitamins, arsenic, iodine, streptomycin, sulfone, thiosemicarbazones, ultraviolet rays, and, in one instance, roentgen irradiation of the mediastinum with two doses of 100 roentgens, had failed. The results of the treatment with nitrogen mustard were as follows: there was a diminution in the size of all the lymph nodes involved, a significant drop in the sedimentation rate, an improvement in general condition which still persists in two patients one year after treatment, and restoration of the temperature to normal. The reaction to the intracutaneous tuberculin test was increased. The white blood corpuscles in the peripheral blood did not undergo pronounced changes, and erythrocytes and hemoglobin remained normal. The authors stress the good results of nitrogen mustard treatment in caseous tuberculous lymphadenitis. The effect is more permanent than that obtained with the same treatment in malignant lymphogranuloma or in leukemic lymphadenosis.

Treatment of Rheumatic Diseases with Extract of Total Adrenal Cortex Combined with Ascorbic Acid.—Fifteen patients, five with subacute articular rheumatism, two with primary chronic polyarthritis, and eight with hypertrophic arthritis, were treated with intravenous injections of extract of total adrenal cortex combined with ascorbic acid. Thirty units of extract of total adrenal cortex and 0.50 gm. of ascorbic acid were administered daily for 10 days. Arterial pressure and blood sugar did not undergo pronounced changes; serum proteins tended to become normal; sedimentation rate, although not restored to normal, dropped, and the hemoglobin content of the blood was improved. Local responses to the treatment were best in patients with subacute articular rheumatism and moderately satisfactory in those with hypertrophic arthritis. Of the two patients with primary chronic polyarthritis, one obtained gratifying results, while treatment failed in the other. Improvement of the general condition was pronounced in all 15 patients. Untoward reactions, consisting of headache, tremor, and rise of temperature, occurred shortly after the first injection, subsided, and did not recur after the following injections. An anti-allergic effect of the treatment is suggested by the fact that the patients were rapidly benefited. The treatment may also have an anti-hyaluronidase action. The high value of the combination of ascorbic acid with extract of total adrenal cortex in the treatment of rheumatic diseases is stressed.

Sickle Cell Crisis in Pregnancy.—Edington describes two cases of sudden death in African primigravidas. Necropsy revealed gross anemia of all organs except for the spleen, which was enlarged, slate blue in color, and packed with sickled erythrocytes. Reid described three similar cases of unexpected death in young African women dying shortly before or after delivery. Emphasis was laid on the enlargement of the spleen and the presence of the sickle-cell trait. There would thus appear to be a syndrome of sudden death: a young primigravida approaching term and regarded as normal suddenly becomes severely ill, with sighing respirations and signs of collapse. Delirium and death occur within two days. At autopsy the pallor of the mother's mucosae and organs contrasts with the dark red appearance of the enlarged, firm spleen and also with the organs and blood of the healthy child, whose hemoglobin level is normal. The histopathological findings exclude malaria and toxemia as causes of death but also differ from the usual descriptions of sickle cell disease in Africa, where emphasis is laid on congestion and thrombosis occurring in the organs utilizing most oxygen, namely, the brain and kidney. It is suggested that the cause of death was an acute sickling crisis, which may have been precipitated by (*a*) hemoconcentration occurring in the later months of pregnancy, and (*b*) the additional oxygen requirements of the child, causing a relative anoxemia in the maternal blood.

BOOK REVIEWS

Pharmacognosy: The Study of Natural Drug Substances and Certain Allied Products. By Robertson Pratt, Ph.D., Associate Professor of Pharmacognosy and Plant Physiology, University of California College of Pharmacy, San Francisco, and Heber W. Youngken, Jr., Ph.D., Associate Professor and Chairman for Pharmacognosy, University of Washington College of Pharmacy, Seattle. Cloth. $8.50. Pp. 644, with 67 illustrations. J. B. Lippincott Company, 227-231 S. 6th St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.C.2; 2083 Guy St., Montreal, 1951.

Pharmacognosy might be defined as the science that treats of the study of natural drug substances and certain allied products. The need for the inclusion of the latter part of the definition signifies the broad field encompassed by this old, but constantly growing, ramification of the medical sciences. The manner in which the authors have been able to present scientifically the facts of such a large field in one textbook, and at the same time make the acquisition of these facts a pleasant literary pursuit, is very commendable and also unusual in a publication of this nature.

The authors make the interesting observation that the study of galls in plants has supplied information that has been applied in the study of growth in general and of tumorous growths in particular. As a result of these studies, plant physiologists may be on the verge of isolating, and perhaps identifying, definite chemical entities which not only serve to stimulate or regulate the rate of growth of tissues but also exercise control over the pattern of growth of the tissues.

The use of sapogenins, known to occur in reasonable amounts in hundreds of species of plants, is posed as a possible starting source for the synthesis of cortisone. It is also noted that research on these plant products might result in the development of new corticosteroid type drugs.

The study of pharmacognosy is fascinating, in view of the fact that the history of drugs and spices is inextricably interwoven with the economic and social life and customs of nations. The authors have done a splendid job of keeping this fact constantly before the reader. The section on antibiotics is an especially welcome addition to a pharmacognosy test as are the sections concerned with measures for pest control and control of fungi, weeds, and other plants.

Developing Democratic Human Relations Through Health Education, Physical Education and Recreation. First Yearbook, American Association for Health, Physical Education and Recreation. Cloth. $4.25. Pp. 562. The Association, 1201 Sixteenth St., N.W., Washington 6, D. C., 1951.

Selected as "the most crucial task facing all educators and leaders of youth today," this subject is developed in a series to which more than 40 writers and editors have contributed. In the introduction it is emphasized that the volume, designated as a yearbook, is only an initial statement of the problem.

Five sections make up the book. In the first section, the basic point of view is elaborated in four chapters that consider democratic behavior and leadership, and the relationships between health education, physical education, and recreation. Successive sections are devoted to development of programs for children, adolescents, older youth, and adults. In all of these, there is presented a four-chapter discussion of the environment, concepts and attitudes that are considered desirable and which should be developed, methods to be employed, and their evaluation.

Many top-flight workers in the field of education served on the editorial committee that provided over-all supervision of the task, and contributors of special chapters are also specialists in this work. Although an apology is offered in the introduction for differences of opinion that might be observed, there is a surprising unanimity among the writers, at least on the basic necessities.

In addition to extensive bibliographies at the end of each chapter, there is a composite alphabetical bibliography at the end of the book, representing a rich source for those wishing to go more deeply into the subject. The volume should be of interest and assistance to workers in this field.

Nutrition and Alcoholism. By Roger J. Williams. Cloth. $2. Pp. 82. University of Oklahoma Press, Norman, 1951.

In this small volume, Dr. Williams presents in nontechnical terms his concept that chronic alcoholism may be a manifestation of a nutritional deficiency. Support for this concept was gained from experiments with laboratory rats. When the animals were offered free choice of water and alcohol, there was considerable individual variation in the amount of alcohol consumed by each rat. However, mild nutritional deficiencies induced by marginal diets led to an increase in alcohol consumption, while correction of these deficiencies resulted in a loss of appetite for alcohol. In subsequent clinical trials, feeding of supplemental vitamins was shown to curb the desire for alcohol in a number of alcoholics. Dr. Williams does not claim to present a universal cure for alcoholism, and readers will doubtless take exception to some of his statements. Nevertheless, he does emphasize a provocative concept, namely, that subtle inborn differences exist between individuals in their fundamental body chemistry and that, as a result, there may be widely differing demands for essential dietary needs. As the author points out, it is not inconceivable that the lack or insufficiency of certain nutritional factors may be involved not only in alcoholism but in susceptibility to infectious diseases or in the etiology of diseases of obscure origin such as arthritis, multiple sclerosis, hypertension, insomnia, cancer, or mental disturbances. Such a concept offers intriguing possibilities in the form of a nutritional approach to the prevention and alleviation of disease.

Rice, Dietary Controls and Blood Pressure with Menus and Recipes. By Frances I. Seymour, M.D. Cloth. $2.95. Pp. 206. Froben Press, Inc., 1776 Broadway, New York 19, 1951.

Dr. Seymour had had an opportunity to observe the effects of the rice diet while undergoing treatment for hypertension. The volume is intended to furnish information to patients about to undergo this rather tedious treatment. Chapters 1 and 2 contain a brief discussion of the necessity for an examination and the various tests employed for diagnosis of essential hypertension. There are chapters devoted to the story of salt and of rice. A valuable feature of the book is the listing of diets for 100 days. The small volume is well written, and the discussion of the various components of the diet are well presented. The book is a worth-while contribution to the important subject of dietetic treatment of hypertension.

Begin Now—to Enjoy Tomorrow . . . By Ray Giles. Cloth. Pp. 57, with illustrations by Will Black. Published as public service by Mutual Benefit Life Insurance Company, P. O. Box 359, Newark 1, N. J., 1951.

Starting with the assumption that the financial aspects of retirement have been given adequate attention, this little volume presents practical suggestions on how to look ahead and set up a program that will be satisfying to both body and mind. In a chapter "What About Money?" the ways in which general expenses are reduced are described. Another chapter presents 10 rules of daily living that probably should be started at age 30 if one is to make the most of old age—or even reach the goal of 65. The volume has a refreshing, practical approach.

Kurzes Lehrbuch der Enzymologie. Von Prof. Dr.Phil. Theodor Bersin. Third edition. Cloth. 19.20 marks. Pp. 274, with 44 illustrations. Akademische Verlagsgesellschaft Geest & Portig K.-G., Sternwartenstrasse 8, (10b) Leipzig C1, 1951.

The latest edition of this well organized textbook for students of the biological sciences, which appears ten years after the second edition, covers the world literature through 1949. A 50-page section on the nature, preparation, dynamics, and biological role of enzymes is followed by 138 pages on individual hydrolytic enzymes and enzymes entering into redox reactions. The last 70 pages are about enzymes in respiration, nutrition, and metabolism of plants and animals, including man. Foreigners who use the work will appreciate the clear, direct style of the writing. There are excellent indexes as well as a full table of contents. The print, illustrations, and binding are good, but most of the paper is poor.

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

QUERIES AND MINOR NOTES

OTOSCLEROSIS AND PREGNANCY

To the Editor:—*A woman of 34, gravida II, para I, has been treated for eight to 10 years by an eye, ear, nose, and throat specialist for otosclerosis. He advised her to avoid becoming pregnant. Now that she shows evidence of being pregnant again, he has insisted that the uterus be emptied. Both the patient and her husband would like another child. The history of dizziness started in the last trimester of her previous pregnancy, in 1938. After delivery, her dizziness became accentuated and became associated with nausea and vomiting. These attacks have been alleviated by the treatment that she received from the nose and throat specialist. I would appreciate an immediate answer.*

Milton H. Cohen, M.D., Lewistown, Pa.

Answer.—Concerning otosclerosis in pregnancy, Greenhill in his "Principles and Practice of Obstetrics" (10th edition) says: "Pregnancy sometimes unfavorably affects diseases of the ear, especially otosclerosis. This disease is a chronic nonsuppurative affection of the bony capsule of the ear surrounding the labyrinth which decreases the capacity to hear. The disease is progressive and heredity is an important factor. From a study of the literature Allen is convinced that difficulties in hearing during pregnancy are frequently overlooked or neglected. A family history of ear disorders should be had from every pregnant woman who experiences changes in hearing. Before progressive deafness is considered an indication for the interruption of gestation, a definite diagnosis of otosclerosis must be made. The otosclerotic condition must be studied during both pregnancy and lactation for counseling as to subsequent pregnancies. Allen believes that usually otosclerosis should not contraindicate marriage or a trial pregnancy, nor should it be considered an indication for therapeutic abortion in primigravidas. On the other hand, a multigravida may have considerable right to question the continuation of her pregnancy, if accurate otologic evidence obtained in previous pregnancies has shown definite and sustained loss of hearing. In Barton's series of 133 women with otosclerosis who experienced one or more pregnancies, 72 per cent suffered loss of hearing with the first pregnancy and 50 per cent with subsequent ones. Barton believes an abortion is never justified for these reasons: 1) The effect of pregnancy on otosclerosis is extremely variable and unpredictable; there is no exact relation between the two conditions. The effect of previous pregnancies is not an accurate index of the possible effect of subsequent ones. 2) The favorable effect of abortion on the otosclerosis is also inconstant. The progression of the deafness with pregnancy may or may not be arrested by abortion. 3) The disease does not endanger the life of the mother as do the accepted indications for therapeutic abortion; for example, tuberculosis, heart disease and toxemia. 4) This type of deafness is not the severe handicap that it once was, owing to the advent of modern hearing aids and the promise of surgical treatment.

"Since the fenestration operation is usually successful there is seldom need to perform a therapeutic abortion because of this condition.

"Sterilization or other eugenic measures are futile in the control of otosclerosis because the hereditary nature of the disease is not known accurately, because it is impossible to prophesy deafness of progeny and because the unfavorable effect of pregnancy on otosclerosis is not constant. In Barton's series, the patients had a 50 per cent chance of having successive pregnancies without further loss of hearing."

THROMBOSIS AND EMBOLISM

To the Editor:—*What is the greatest interval reported between thrombophlebitis and embolism?*

Erwin R. Kaback, M.D., *Otisville, N. Y.*

Answer.—The question cannot be answered categorically by quoting figures from the literature for the following reasons. First, roughly 50 per cent of pulmonary emboli occur before the clinical manifestations of venous thrombosis. The peripheral thrombus is silent and may grow by apposition after the pulmonary embolus. Second, cases like that of Strauss (cited by de Takats in Brahdy and Kahn's "Trauma and Disease" ed. 2, Philadelphia, Lea & Febiger, 1941, p. 115) of a man who died of pulmonary embolism three months after fracturing his patella, are clouded by the fact that the original thrombosis may recur and that the embolus may be due to a recent growth of an old thrombus or even to a silent unrecognized thrombus from the pelvis, from the opposite extremity or from the heart.

With these reservations one might state that an embolus may occur even years after an injury or after a thrombosis and still be causally related to it, provided, however, that in the interval one or more attacks of recurring thrombosis were recognizable. The fresh thrombus retracts from the wall and is then organized in two to three weeks. It is possible that the rate and extent of clot retraction have to do with embolization. (Quick and Hussey, *Science* 112:558, 1950.)

ALOPECIA TOTALIS

To the Editor:—*A 26 year old, single man has no hair on the body. He has been having this trouble about 10 years. He does not have any symptom of leprosy. Kahn and Wassermann reactions were negative. While he denies a history of syphilis, once, he said, he received more than 10 injections of neoarsphenamine and injections of male hormone. He has also used many kinds of stimulative ointments to the scalp and ultraviolet, which did not appear to be helpful. Please give me an accurate diagnosis and effective treatment.*

C. L. Chu, M.D., Sanator, S. D.

Answer.—It would appear that a person who has no hair on his body has what is known as alopecia totalis, the cause for which is not known. Repeated search for glandular deficiencies of one type or another and efforts at hormonal therapy have in the main been unsuccessful. In women with alopecia totalis the hair frequently grows back during pregnancy but again disappears completely when the child is weaned. In view of the fact that the cause of alopecia totalis is not known, there is no specific treatment for it, but it does seem advisable to encourage persons who have total alopecia to accept it, not to be ashamed of it: women especially should be encouraged to wear wigs.

PARADOXICAL EMBOLISM

To the Editor:—*An injured person claims that an embolus that occurred in the femoral artery was due to a blood clot that followed a minor injury to a vein in the left arm. The heart specialist claims that the embolus entered the right auricle, passed through the foramen ovale and then part of the clot entered the coronary and the other part lodged in the right femoral artery, causing an embolism which necessitated amputation of the right leg. Can you tell me whether any such case has been recorded?*

Robert M. Burns, M.D., St. Paul.

Answer.—The auricular system may stay patent after birth as a patent foramen ovale. This defect varies from a small slit, covered by a valvelike membrane, to a large oval opening. A systolic murmur is usually present with an accentuated second

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

sound at the pulmonary area; occasionally the soft diastolic murmur of pulmonary insufficiency may be heard. Roentgenologically there is an enlargement of the right auricle, right ventricle and the pulmonary artery. The hilar pulsations may be accentuated. The electrocardiogram shows right axis deviation, and auricular fibrillation often occurs. All these findings, of course, presuppose a large defect.

Ingham (*Am. J. M. Sc.* **196**:201, 1938) reviewed the literature on paradoxical embolism and reported six cases, in each of which an autopsy demonstrated an embolus in transit through a patent foramen ovale.

Obviously, if the diagnosis of paradoxical embolus is to be maintained, one must search for in vivo evidence of patent foramen ovale, which may have to include cardiac catheterization; other frequent causes of embolism due to myocardial infarction or auricular fibrillation must be excluded. Paradoxical embolism constitutes roughly 1 per cent of cases in which sudden arterial occlusion occurs.

NEUROLOGIC COMPLICATIONS OF INFECTIOUS MONONUCLEOSIS

To the Editor:—*A 23 year old man had urinary retention. He had been sick for 10 days, complaining of sore throat, chills, fever and some stiffness of the neck, mostly on the right side. Examination revealed postcervical adenopathy on the right side, pharyngitis and tonsillitis. The temperature was 101 F. Laboratory data, including spinal fluid findings, substantiated the diagnosis of infectious mononucleosis with central nervous system involvement. Abdominal and cremasteric reflexes were absent; other reflexes were normal. Cystometric studies revealed an atonic type of neuromuscular vesical dysfunction, also seen on intravenous urography. What are the neurologic complications of infectious mononucleosis, the pathology and prognosis?*

Victor J. Mulaire, M.D., Stamford, Conn.

Answer.—Answers to this query are given in a recent paper on "Nervous System Involvement in Infectious Mononucleosis," by Bernstein and Wolff (*Ann. Int. Med.* **33**:1120, 1950). Apparently the nervous system is not often affected. Reports of 34 instances were collected among which were examples of serous meningitis, encephalitis, meningoencephalitis and acute polyneuronitis. In one instance the patient had difficulty in voiding as noted in the query. Since the disease rarely is fatal, few necropsy reports are available. Studies of the brain in three cases show the nonspecific changes of a viral-like infection (*Am. J. Path.* **23**:463, 1947; *Blood* **2**:217, 1947). The prognosis is good; complete recovery occurred in 85 per cent of cases.

TREATMENT OF BURSITIS

To the Editor:—*What is the percentage of cases of acute calcific bursitis cured by the following measures: (1) diathermy, (2) x-ray therapy, and (3) procaine hydrochloride injections into the bursa, with and without irrigation of the bursal sac? What are the results with these measures in chronic calcific bursitis?*

Benjamin H. Archer, M.D., New York.

Answer.—There are no acceptable statistics which would establish the efficiency of these various measures on a percentage basis in either acute or chronic calcific bursitis. Diathermy should not be used in acute bursitis, with or without the presence of calcium. Diathermy increases the hyperemia, and this is likely to cause an increase in pain. In acute bursitis with some calcium in the fluid within the bursa, elimination of tension due to the pressure of the fluid contents of the bursa affords the quickest possible relief. This can be obtained by injection of procaine and repeatedly needling the bursa to make small openings, so that the fluid can leak out into surrounding tissue, where it may be picked up by the circulation. The percentage of good results from this procedure would be about the same as results when two needles are used and saline or procaine solutions are washed through the bursa. A considerable number of orthopedic surgeons now favor the use of x-rays after procaine injections and fenestration of the bursa, with or without irrigation of the bursal sac. This combination has been successful in a high percentage of cases in which the condition was definitely acute.

In the older and truly chronic calcified bursa, conservative measures are less likely to be successful. Diathermy in this chronic phase may be soothing and may aid in the absorption of the calcified material. It should be noted, however, that old, dry, calcified deposits are rarely found in the bursae about the shoulders. These calcified deposits are usually within the tendon of the supraspinatus muscle. Most acute bursae associated with calcification are secondary to an injury of the fibers of the supraspinatus tendon, and it is in the torn or fragmented fibers of this tendon that calcification most often takes place. Since the bursa lies directly over the tendon, it is possible for some of the calcium to escape into the bursa through a small tear or rent in the bursal wall. In the old, chronic, calcified supraspinatus tendons, with or without persistent bursitis, the calcium is usually dry or of the consistency of cheese. In such instances it cannot be removed by irrigation, multiple needling, diathermy, or x-ray therapy. An operation for exposing the tendon and thoroughly excising the calcified areas and, when indicated, repair of the tendon is usually followed by relief of symptoms and complete cure.

FIBROUS CAVERNOSITIS

To the Editor:—*I have a 40 year old patient who has a small fibrous tissue area in the midportion of the penis, obliterating about 2 cm. of one section of the corpus cavernosum. He complains of pain at the site of the lesion and deformity of the organ on erection. There is no roentgen evidence of calcification. What is the most likely cause, other than injury, and what is the treatment?*

Hugh L. Houston, M.D., Murray, Ky.

Answer.—In all probability the penile lesion described is caused by fibrous cavernositis (Peyronie's disease). This lesion is generally regarded as resulting from a chronic inflammatory process in the sheaths or intracavernous septums of the corpora cavernosa. The fibrous process usually involves Buck's fascia and the adjacent tissues. One or more fibrous plaques, which are readily palpable as firm nodules of variable extent, may result. The lesion often causes penile deformity as described and in some cases is the cause of pain. The fibrous plaques can usually be distinguished from gumma or malignant lesions by the intense hardness of the area and the absence of other clinical data. As a rule the process gradually becomes circumscribed and the local symptoms subside. Good results have been obtained in some cases by surface applications of radium. A mixture of tocopherol acetates (tofaxin®) has been administered, 50 mg. three times daily, with variable results. This drug consists largely of synthetic vitamin E, the value of which is thus far unestablished. Although surgical excision has been employed, the results obtained have often been unsatisfactory.

HYPERGLYCEMIA AND FURUNCULOSIS

To the Editor:—*What is the significance of a fasting blood sugar of 140 mg. per 100 cc. in a 30 year old, obese male—weight 260 pounds (118 Kg.)—with furunculosis. He has no glycosuria normally. The dextrose tolerance curve is of the diabetic type, reaching 180 mg. per 100 cc. at 30 minutes, at which time there is glycosuria, 240 mg. at 1 hour and 180 mg. at 2 hours. Is insulin indicated?*

Wendell W. White, M.D., Faith, S. D.

Answer.—Hyperglycemia, both fasting and during a glucose tolerance test, accompanied by glycosuria implies diabetes. In this instance the furunculosis should be eliminated before a permanent diagnosis is made. If the patient cannot remain sugar free and have a normal blood sugar level on a diet of about 200 Gm. of carbohydrate, 1 Gm. of protein per kilogram and 80 Gm. or less of fat while the weight is being reduced to within at least 30 pounds (13 Kg.) of standard for his height, then he should take insulin.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, MAY-AUGUST 1951

Titles have been listed or abstracts made of important articles in the following journals in the Current Literature Department of THE JOURNAL during the past four months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in Continental United States and Canada and to members of the American Medical Association for a period not exceeding five days. Three journals may be borrowed at a time. No journals are available prior to 1940. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation; "E," Editorial; "C," Correspondence; "ab," abstracts; the asterisk (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For the author index see page 1671.

POSTAGE STAMPS
  French honor military medicine scientists, 1240
POSTGRADUATE: See Education, Medical, graduate
POSTNATAL: See Infants, Newborn
POSTOPERATIVE: See Surgery
POSTPARTUM: See Puerperium
POSTURE
  physiological position for delivery: squatting position, [Howard] 680—ab
POTASSIUM
  arsenite: Fowler's solution; its total amount of arsenic; cause cancer? 418
  deficiency in bulbar poliomyelitis; relief with potassium chloride, [Lans & others] *1017
  hydrochloride vs. basic fuchsin staining technic in fungus infections, [Kligman & Mescon] *1564
  in Blood: See Blood
  iodide and streptomycin combined, in tuberculosis of lung, [Woody] 1258—ab
  metabolism and digitalis toxicity in heart failure, 1030—E; [Lown] 1447—ab
  Penicillin: See Penicillin G
  salts treatment of periodic paralysis, [Hammes] *1401
POTATOES
  Heinz Strained Sweet Potatoes, 477
POULTRY: See Chickens
POWDER: See Dusting Powder
POWER, Atomic: See Atomic Energy
PRACTICAL NURSING: See Nurses and Nursing
PRACTICE of Medicine: See Medicine, practice
PRACTITIONER: See Physicians
  Drugless: See Cults
PRECEPTORSHIPS
  A.M.A. resolution on, 850
PREECLAMPSIA: See Eclampsia
PREFRONTAL Leukotomy; Lobotomy: See Brain surgery
PREGNANCY: See also Fertility; Fetus; Labor; Maternity; Obstetrics; Placenta; Puerperal *Infection; Puerperium*
  air transport of pregnant women, 253—ab
  complications; acute cholecystitis, [Buxton & others] *301
  complications: anemia, intravenous iron for, [Scott] 684—ab
  complications: anemia, response to penicillin G, [Foy] 1539—ab
  complications: ankylosing spondylitis, [Hart] 1352—ab
  complications: diabetes, 909—ab
  complications: essential hypertension, [Nordenstrahl] 1268—ab
  complications: familial erythroblastosis, abortion and castration indicated? [Dahr] 1355—ab
  complications: heart disease, adequate care evaluated, [Fitzgerald & others] *910
  complications: hyperthyroidism, 222
  complications: illness in first trimester, [Hartman] 1075—ab
  complications: malaria, quinine treatment advisable? (reply) [King] 510
  complications: measles; congenital malformations in child, Sweden, 1339
  complications: otosclerosis, abortion indicated? 1619
  complications: peptic ulcer, why is it rare during pregnancy? [Schmid] 504—ab
  complications: ptyalism, 1545
  complications: rabies vaccine given during 7th month not cause of deformity in child, 1458
  complications: renal failure after hemorrhage, [Tennent] 1450—ab
  complications: rheumatoid arthritis aggravated, 1364
  complications: sickle cell crisis, [Eddington] 1617—ab
  complications: toxic neuritis, 299
  complications: tuberculosis, infants born of tuberculous mothers, [Ratner] 965—ab
  complications: typhoid, chloramphenicol for, [Stevenson & others] *1190
  cortisone and gestation, Paris, 493
  cortisone, hay fever and, 1089
  diagnosis, biologic tests, Denmark, 277
  diagnosis, clinical experiences with Mainini and bufo pregnancy tests, [Felding] 875—ab
  diagnosis, comparative Galli-Mainini and Friedman reactions, [Felding] 875—ab
  diagnosis test with male toad, [Tien] 503—ab
  diagnosis test with neostigmine (prostigmine), 415
  duration, relation to prematurity, [Toback] *897
  ectopic, culdocentesis, [Beacham] 64—ab
  ectopic, incidence, [Anderson] 675—ab
  ectopic, posterior colpotomy in, [Draa] 675—ab
  ectopic, rupture of, [Cezar de Andrade] 288—ab
  edema in, mercurial diuretics advisable to control? 415
  endocrine patterns (4 types) in term pregnancies after abortion, [Jones & Delfs] *1212
  hormonal balance of pregnancy and menopause compared, 1544
  Interruption of: See Abortion
  iron metabolism in, [Chapman] 1156—ab
  Multiple: See Superfetation; Triplets; Twins
  postpartum plasma for rheumatoid arthritis, [Granirer] *995
  Protection From: See Contraception
  rabies transmitted by pregnant dog possible? 1175
  result from deposition of sperm on vulva without intromission? (reply) [Kelly] 692
PREGNANCY—Continued
  Toxemia of: See also Eclampsia
  toxemia of, 1124—ab
  toxemia of, blood pressure in, [Bukherjee] 70—ab
  toxemia of, cause of maternal deaths in New York City, [Falson] *1393
  toxemia of, cause of maternal deaths in rural South, [Ferguson] *1388
  toxemia of, hypertension in, gonadotropin concentration in serum, [Govan] 1540—ab
  toxemia of: nausea and vomiting, treatment, 417
  toxemia of, routine examination of ocular fundi, [Gordon] *810
  Urine, Hormone Excreted in: See Gonadotropins, chorionic
  urine, paper chromatography of, [Zilliacus] 1082—ab
PREGNANEDIOL
  deficiency, in term pregnancies following abortion, [Jones & Delfs] *1212
PREGNENOLONE
  toxicity: cutaneous side effects, [Brunner] 1346—ab
  treatment of rheumatoid arthritis, [Brugsch] 1348—ab; [Norcross] 1349—ab
PREMATURE INFANTS: See Infants, premature
PREMEDICAL Work: See Education, Medical
PRENATAL: See Fetus; Pregnancy
  Injury: See Medicolegal Abstract at end of letter M
PREPAREDNESS, Medical: See Medical Preparedness
PREPAYMENT Plans: See Hospitals, expense insurance; Medical Service Plans
PRESCRIPTIONS
  physicians overprescribing barbiturates, [Barhash] *1584
  refilled, federal legislation proposed, 1427
PRESENTATION: See Labor, presentation
PRESS: See Newspapers
PRESSURE
  glass float device to prevent air embolism in transfusions under, [Wilkinson] *1318
  positive, for nebulization with vaccum cleaner, [Sheldon & others] *648
  positive pressure air lock in resuscitation in asphyxia neonatorum, [Bloxsom] *1120
PREVENTIVE MEDICINE: See also Immunization; Vaccination
  advances in, 1028—ab
  integral and necessary part of everyday practice, 729—ab
PRICE-JONES curve in hemolytic disease of newborn, [deVries] 503—ab
PRICELESS Frozen Concentrated Orange Juice, 108
PRISCOLINE: See Benzazoline
PRISONERS: See Criminals
PRIZE FIGHTING: See Boxing
PRIZES: See also Fellowships; Lectures; Scholarships
  Allen (Raymond B.) Instructorship Awards, 946
  Alvarenga, 1139
  American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Foundation Prize, 569
  American Cancer Society, 205; 738; 740
  American Dermatological Association, 1055
  American Heart Association gold hearts awarded, 1518
  A.M.A. Committee on Awards, 1036
  A.M.A. Distinguished Service Award, (nominations open) 38—E; (to Dr. Allen O. Whipple) 735—E; (balloting) 831
  American Medical Golfing Association awards, 1055
  American Otological Society, 1141
  American Physicians Art Association awards, 1142
  American Society of Plastic and Reconstructive Surgery, 661
  Auerbach Award, 204
  Awards for Distinguished War Service: See Korean War, Heroes; World War II, Heroes
  Blackwell Medal, 738
  Borden Award in nutrition, 266
  Borden Undergraduate Research Award, 1239
  Capps, 567
  Chapin Medal, 486
  Commendation for War Service: See Korean War, Heroes; World War II, Heroes
  Commercial Solvents Award, 658
  Criss, 856
  Crookshank (Comfort) Award for cancer research, 1139
  De Roaldes gold medal, 1053
  Fisher Memorial Award, for discovering Coxsackie virus, 1240
  Friedenwald Medal, 1055
  Gibbs Medal, 41
  Goldberger Award, 657
  Gold-Headed Cane, Calif., 1331
  Hillebrand Prize, 204
  Hofheimer Award, 737
  Ill (Edward J.), 1140
  Kappa Delta, 661
  Keyes memorial medal, Alaska, 1602
  Knudsen Award, 658

PRIZES—Continued
  Laennec Society, Pa., 1054
  Longacre Award, 667
  Marchman Award, Texas, 206
  Miller (Leo F.) to students, Illinois, 855
  Mount Sinai Hospital awards for interns, Illinois, 41
  National Safety Council's Public Interest Award to A.M.A.'s Today's Health, 486
  National Traffic Safety Contest winners, 207
  Neuberg Medal Award, 205
  New Jersey Orthopedic Society Award, 1140
  Paul-Lewis Laboratories Award, 267
  Remington Medal, 485
  Ricketts, 567
  Schering Award, 949
  Shattuck Award, 383
  Smith (Theobold) Award, 1239
  Strittmatter Award, 385
  Trudeau Medal, New York, 659
  Van Meter, 1147
PROBENECID (Benemid)
  name recognized by Council, 927
PROCAINE AMIDE (pronestyl)
  action in cardiac arrhythmias, [Miller & others] *1104
  treatment of ventricular tachycardia, [Irvin & Cutts] *1282
PROCAINE HYDROCHLORIDE
  block of cervical sympathetic in cerebral concussion, [Blumensaat] 1359—ab
  block of stellate ganglion in shoulder-hand syndrome after myocardial infarction, [Swan & McGowan] *774
  dermatitis from local anesthetics, [Lane & Luikart] *717
  intravenous as diuretic in toxemia, [Serwer] 65—ab
  intravenous, cardiotoxic action, [Carter] 1532—ab
  Penicillin: See Penicillin treatment
  to overcome pain of injections of liver extract or vitamins, 77
  treatment of osteoarthritis, [Berger] 679—ab
PROCTITIS: See Rectum inflammation
PROCTOLOGY: See also Rectum
  International Academy of, 3rd annual convention, 206
PROFESSION: See also Medicine, profession of
  basic values in professional education, [Severinghaus] *79
  income of lawyers and dentists compared with physicians, 1237—E; (Bureau article) [Dickinson & Bradley] *1251
  retirement benefits for professional persons, A. M. A. resolution on, 849; 1598—E
PROGESTERONE
  Excretion Product of: See *Pregnanediol*
  treatment of acne vulgaris, [Andrews & others] *1107
  treatment of neurodermatitis, 300
  treatment of sex disturbances, [Kaufmann] 1355—ab
PROLAPSE: See Spine, intervertebral disk; Urethra
PROMIN: See Glucosulfone
PRONESTYL: See Procaine Amide
PROPYLPARABEN
  treatment of Rhus dermatitis, [Hoagland & others] *612
PROPYLTHIOURACIL
  toxicity: hypoprothrombinemia, [Craddock] 1262—ab
PROSTATE
  cancer, do androgens initiate? 300
  cancer, estradiol pellet implantation in, [Okie] 680—ab
  Inflammation: See Prostatitis
  obstruction: use of diethylstilbestrol on noncancerous type, 766
PROSTATECTOMY
  mortality rate in transurethral prostatic resection, [Creevy] 1611—ab
  retropubic: Millin technic modified, [Carruthers] 1533—ab
PROSTATITIS
  chronic, and oligospermia, 768
PROSTHESIS: See Limbs, Artificial
PROSTIGMINE: See Neostigmine
PROSTITUTES
  examination and certification of, A.M.A. position on, 564—E
PROSYMPAL
  hormonal cerebral vasopressor substance, 1326—E
PROTEIN: See also Amino Acids; Meat; Pork
  diet (high) low-carbohydrate diet for obesity, [Billig] *1180
  diet (high) plus iron therapy for anemia in blood donor, [Bateman] 402—ab
  in Blood: See Blood
  Sensitivity: See Allergy
PROTEUS
  vulgaris, effect of combinations of antibiotics, [Armstrong] 1160—ab
PROTHROMBIN: See Blood prothrombin
PSEUDOAPPENDICITIS
  symptoms in, tuberculous peritonitis, [Mazzi] 685—ab
PSEUDOHERMAPHRODITISM: See Hermaphroditism
PSEUDOMONAS
  aeruginosa, effect of combinations of antibi- [illegible] 0—ab
F [illegible] 1170—ab
PSITTACOSIS
  treatment, aureomycin, [Hamke] 968—ab
PSORIASIS
  treatment, nitrogen mustard [Gómez Orbaneja] *1269—ab*
  treatment, undecylenic acid by mouth, [Rattner & *Rodin*] *1113
PSYCHE: See *Personality*
PSYCHIATRISTS
  referring your *patient to* a psychiatrist [Flumerfelt] *1589
PSYCHIATRY: See *also* Hospitals, psychiatric; Mental Disorders; Mental Hygiene; Neuropsychiatry; *Psycho*—
  child, Angry Boy, (film review) 1440
  child, fellowships in, 741
  clinical, and mental test methods, Paris, 955
  course in *psychiatric* nursing at Saint Elizabeths Hospital, 211

VENTILATION
  - Hyperventilation: See Respiration

VENTRICULAR TACHYCARDIA: See Tachycardia

VENTRICULOSTOMY: See Brain surgery

VERILOID
  - hypotensive action, [Kauntze] 1080—ab

VERRUCA
  - inclusion bodies in warts, [Lyell] 1354—ab
  - plantar, resurfacing foot by plastic surgery, [Brown & Fryer] *628

VERTEBRAE: See Spine

VERTIGO
  - aural, decompressive trephining of subarachnoidal cisterns for, [Piquet] 292—ab
  - hypoglycemic tendency with, [Harrill] 678—ab

VESICATION: See Blister

VETERANS: See also American Legion
  - benefits for Korean war veterans, 482
  - beriberi heart in, Ia., [Gutenkauf] 871—ab
  - malaria in Korean war veterans, 1523; 1602
  - Medical Care: See also Hospitals, veterans
  - medical care, chiropractors in VA, [Humphrey] 280—C
  - medical care of tuberculous veteran, continuing problem, [Barnwell] *1372
  - service for those who stutter, 667
  - spinal cord and cauda equina injuries in, management, [Pollock] *1551
  - "wheelchair" homes for, 1436

VETERANS ADMINISTRATION
  - activities, A.M.A. Board of Trustees report on, 939
  - consultants, 2 appointed, 1147
  - Hospitals under control of: See Hospitals, veterans
  - National Advisory Committee affiliated with, 667
  - physicians wanted for, 1147
  - presumption of service connected disability, 382; 1427

VETERINARIAN
  - danger of contracting rabies from operating on rabid dog or cow? 1175

VINCENT'S Infection: See Angina, Vincent's

VINEGAR
  - eel in sputum, [De May & others] *645

VINYLIDENE
  - chloride resins, 768

VIOMYCIN
  - absorption and excretion, [Werner] 681—ab

VIRGINIA, Tuberculosis Foundation of: See Foundations

VIRILISM: See Hermaphroditism

VIRUS: See also Influenza; Poliomyelitis
  - amicrobic urethritis in men, [Tissot] 972—ab
  - Coxsackie: See Coxsackie Disease
  - cortisone concentration in eggs and, [Kilbourne] 215—ab
  - course in techniques in virology, 483
  - disease, cytologic smears in diagnosis, [Blank & others] *1410
  - Hepatitis: See Liver Inflammation
  - mumps virus in human milk and in milk of infected monkey, [Kilham] *1231

VISAMMIN: See Khellin

VISCERA
  - lesions in scleroderma, [Gil] 1257—ab

VISION: See also Eyes; Glasses; Ophthalmology
  - acuity of teacher, (reply) [Foote] 510
  - Color: See Color Blindness
  - course in sight saving and Braille, District of Columbia, 483
  - effect of photoflash on, 1456
  - industrial, conference on, Indiana, 265
  - Loss of: See Blindness
  - problems of supersonic speeds, [Byrnes] 675—ab
  - See Better: Healthy Eyes, (film review) 58
  - testing, screening school children for errors: use of Massachusetts test and Snellen test, 1364

VISUAL EDUCATION: See Moving Pictures

VITAL CAPACITY
  - in poliomyelitis, measurement of, [Plum & Wolff] *442

VITAL STATISTICS
  - birth rates (world), 569
  - Death Certificates: See Death
  - Death Rate: See also Infants, mortality; Life expectancy; Maternity, mortality; under names of specific diseases as Tuberculosis
  - death rates decline in many countries, 1055
  - death rates from detectable chronic diseases, United States, 1948, [Levin] *1398
  - death rates, male and female, England, 863
  - filmstrip on, 1427

VITAMINS
  bacterial (new), 1327—E
  concentrate not cause of osteoarthritis of spine, 1366
  in frozen orange juice concentrate, (A.M.A. Council report), 35; 37—E
  injections, procaine to overcome pain of, 77
VITAMINS A
  hypervitaminosis, case in adult, [Sulzberger & Lazar] *788
  hypervitaminosis with infantile cortical hyperostosis, [Rineberg & Gross] *1222
  poisoning (chronic) from overdosage of percomorph liver oil, [Bair] *1573
  poisoning in young children, [Gribetz] 1076—ab
  treatment of dark adaptation, [Niedermeier] 760—ab
  treatment of deafness, [Lobel] 1441—ab
VITAMIN B COMPLEX: See also Acid, *p*-aminobenzoic; Acid, folic
  B_1: *See also Acid, nicotinic; Thiamine Hydrochloride*
  B_1, Modest Miracle, (film review) 1255
